#### AnOpen-sourceCryptographicCoprocessor

## PeterGutmann UniversityofAuckland,Auckland,NewZealand pqut001@cs.auckland.ac.nz

#### **Abstract**

Current cryptoimplementationsrelyonsoftware runningundergeneral-purposeoperatingsystems alongsideahordeofuntrustedapplications, ActiveX controls, webbrowser plugins, mailershandling messageswithembeddedactivecontent, and numerous otherthreatstosecurity.withonlythe almost nonexistant)securitytokeepthetwoapart.This paperpresentsageneral-purposeopen-sourcecrypto coprocessorcapableofsecurelyperformingcrypto operationssuchaskeymanagement, certificate creation andhandling, and emailencryption, decryption, and signing, at a cost one to two orders of magnitude below thatofcommercialequivalentswhileproviding generallyequivalentperformanceandahigherlevelof functionality. The paper examines various issues involvedindesigningthecoprocessor, and explores optionsforhardwareaccelerationofcryptooperations forextendedperformanceaboveandbeyondthat offeredbythebasiccoprocessor's COTS hardware.

### 1. ProblemswithCryptoonEnd-user Systems

Themajorityofcurrentcryptoimplementationsrun undergeneral-purposeoperatingsystemswitha relativelylowlevelofsecurity, alongsidewhich exista limited number of smart-cardassisted implementations which store a private keyin, and perform private-key operations with, a smart card. Complementing these are an even smaller number of implementations which perform further operations indedicated (and generally very expensive) hardware.

Theadvantageofsoftware-onlyimplementationsisthat theyareinexpensiveandeasytodeploy. The disadvantageoftheseimplementationsisthatthey provideaverylowlevelofprotectionfor cryptovariables, and that this low level of security is unlikelytochangeinthefuture.ForexampleWindows NTprovidesafunction ReadProcessMemorywhich allowsaprocesstoreadthememoryof(almost)any otherprocessinthesystem(thiswasoriginallyintended toallowdebuggerstoestablishbreakpointsand maintaininstancedataforotherprocesses[ 1]),allowing bothpassiveattackssuchasscanningmemoryforhighentropyareaswhichconstitutekeys[ 2]andactive attacksinwhichatargetprocesses'codeordatais

modified(incombinationwith VirtualProtectEx, whichchangestheprotectiononanotherprocesses' memorypages)toprovidesupplementalfunctionalityof benefittoahostileprocess.By applicationsuchastheWindowsshell,thehostile processcanreceivenotificationofanyapplication (a.k.a. "target") starting upor shutting down, after whichitcanapplythemechanismsmentioned previously. Avery convenient way to do this is to subclassachildwindowofthesystemtraywindow, yieldingasystem-widehookforinterceptingshell messages[3]. Anotherway to obtain access to other processes'dataistopatchtheuser-to-kernel-mode jumptableinaprocesses'ThreadEnvironmentBlock (TEB), which is shared by all processes in the system ratherthanbeinglocaltoeachone, so that changing it inoneprocessaffectseveryotherrunningprocess[ 4].

Althoughtheuseoffunctionslike ReadProcessMemoryrequiresAdministrator privileges, mostuser stendtoeitherruntheir systemas Administratororgivethemselvesequivalentprivileges sinceit's extremely difficult to make use of the machine withouttheseprivileges.Intheunusualcasewherethe userisn'trunningwiththeseprivileges, it's possible to useavarietyoftrickstobypassanyOSsecurity measureswhichmightbepresentinordertoperform thedesiredoperations. For example by installing a Windowsmessagehookit'spossibletocapture messagesintendedforanotherprocessandhavethem dispatchedtoyourownmessagehandler.Windows thenloadsthehookhandlerintotheaddressspaceof theprocesswhichownsthethreadwhichthemessage wasintendedfor,ineffectyankingyourcodeacross intotheaddressspaceofthevictim[ 5].Evensimpler aremechanismssuchasusingthe HKEY\_LOCAL\_MACHINE\Software\Microsoft\Windows NT\CurrentVersion\Windows\AppInit\_DLLskey,which specifiesalistofDLLswhichareautomaticallyloaded andcalledwheneveranapplicationusesthe USER32 systemlibrary(whichisautomaticallyusedbyallGUI applications and many command-lineones). Every DLLspecifiedinthisregistrykeyisloadedintothe processes'addressspaceby USER32, which then calls the DLL's DllMainfunction to initialise the DLL (and, byextension,triggerwhateverotheractionstheDLLis designedfor).

Amoresophisticatedattackinvolvespersuadingthe systemtorunyourcodeinring0(themostprivileged securitylevelusuallyreservedfortheOSkernel)or, alternatively, convincing the OS to allowy out oloada selectorwhichprovidesaccesstoallphysicalmemory (underWindowsNT,selectors8and10providethis capability).Runningusercodeinring0ispossibledue tothepeculiarwayinwhichtheNTkernelloads.The kernelisaccessedviathe int2Ehcallgate,which initiallyprovidesabout200functionsvia NTOSKRNL.EXEbutisthenextendedtoprovide moreandmorefunctionsassuccessivepartsoftheOS areloaded.Insteadofmerelyaddingnewfunctionsto the existing table, each new portion of the OS which is loadedtakesacopyoftheexistingtable,addsitsown functionstoit, and then replaces the old one with the newone. To add supplemental functionality at the kernellevel, all that's necessary is to do the samething [6].Onceyourcodeisrunningatring0,anNTsystem startslookingalotlikeamachinerunningDOS.

Althoughtheproblemsmentionedsofarhave concentratedonWindowsNT,manyUnixsystems aren'tmuchbetter.Forexampletheuseof ptrace withthePTRACE ATTACHoptionfollowedbythe useofother ptracecapabilitiesprovidessimilar headachestothosearisingfrom ReadProcessMemory.Thereasonwhytheseissues are more problematic under NT is that users arepractically forced to run with system Administratorprivilegesinordertoperformanyusefulworkonthe system, since a standard NT system has no equivalent toUnix's sufunctionalityand,tocomplicatethings further, frequently assumes that the useral ways has Administratorprivileges(thatis,itassumesit'sa single-usersystemwiththeuserbeingAdministrator). Whileit'spossibletoprovidesomemeasureof protectiononaUnixsystembyrunningcryptocodeas adaemoninitsownmemoryspace, the fact that the AdministratorcandynamicallyloadNTservices(which canuse ReadProcessMemorytointerferewithany otherrunningservice)meansthatevenimplementing thecryptocodeasanNTserviceprovidesnoescape.

#### 1.1. The Root of the Problem

Thereasonwhyproblemslikethosedescribedabove persist, and whywe'reunlikely to eversee are ally secure consumer OS is because it's not something which most consumers care about. One recent survey of Fortune 1000 security managers showed that although 92% of them were concerned about the security of Javaand Active X, nearly three quarters allowed the monto their internal networks, and more than half didn't even bothers canning for them [Users are used to programs malfunctioning and computers crashing (every Windows NT user cantell

youwhattheabbreviationBSODmeanseventhough it's never actually mentioned in the documentation), andseeitasnormalforsoftwaretocontainbugs.Since programcorrectnessisdifficultandexpensiveto achieve, and as long as flashiness and features are the majorsellingpointforproducts, buggyandinsecure systems will be the normal state of affairs [ 8].Unlike otherMajorProblemslikeY2K(whichcontaintheir ownbuilt-indeadline), security generally isn't regarded asapressingissueunlesstheuserhasjustbeen successfullyattackedorthecorporateauditorsareabout topayavisit, which means that it's much easier to defer addressingittosomeothertime[ 9].Evenincases wherethesystemdesignersoriginallyintendedto implementarigoroussecuritysystememployinga trustedcomputingbase(TCB),therequirementtoadd featurestothesysteminevitablyresultsinallmannerof additionsbeingcrammedintotheTCB, with the result thatitisneithersmall,norverified,norsecure.

AnNSAstudy[ 10]listsanumberoffeatureswhichare regardedas"crucialtoinformationsecurity"butwhich areabsentfromallmainstreamoperating systems. Featuressuchasmandatoryaccesscontrolswhichare mentionedinthestudycorrespondtoOrangeBookBlevelsecurityfeatureswhichcan'tbeboltedontoan existingdesignbutgenerallyneedtobedesignedin from the start, necessitating a complete overhaulofan existingsysteminordertoprovidetherequired functionality. This is often prohibitively resourceintensive, for example the task of reengineering the Multicskernel(whichcontaineda"mere"54,000lines ofcode)toprovideaminimisedTCBwasestimatedto cost\$40M(in1977dollars)andwasnevercompleted [11]. The work involved in performing the same kernel upgradeorredesignfromscratchwithanoperating systemcontainingmillionsortensofmillionsoflines ofcodewouldmakeitbeyondprohibitive.

Atthemomentsecurityandeaseofuseareatopposite endsofthescale, and most users will optfore a seofuse oversecurity.JavaScript,ActiveX,andembedded activecontentmaybeasecuritynightmare, buttheydo makelifealoteasierformostusers, leading to commentsfromsecurityanalystslike"Youwantto writeupareportwiththelatestversionofMicrosoft Wordonyourinsecurecomputeroronsomepieceof iunkwithasecurecomputer?"[ 12],"Whichsellsmore products:reallysecuresoftwareorreallyeasy-to-use software?"[13],and"It'spossibletomakemoneyfrom alousyproduct[...]Corporateculturesarefocusedon money,notproduct"[ 14].Inmanycasesusersdon't evenhaveachoice, if they can't process data from Word.Excel.PowerPoint.andOutlookandviewweb pagesloadedwithJavaScriptandActiveX,their businessdoesn'trun,andsomecompaniesgosofaras topublishexplicitinstructionstellingusershowto

7].

disablesecuritymeasuresinordertomaximisetheir web-browsingexperience [15]. GoingbeyondbasicOS security, mostcurrentsecurityproductsstilldon't effectivelyaddresstheproblemsposedbyhostilecode suchas trojanhorses (which the Orange Book's Bell-LaPadulasecurity model was designed to combat), and the systems the coderuns on increase both the power of the code to other systems.

Thispresentsratheragloomyoutlookforsomeone wantingtoprovidesecurecryptoservicestoauserof thesesystems. Inordertosolvethisproblem, weadopt areversedformofthe Mohammed-and-the-mountain approach: Insteadoftrying tomove the insecurity away from the cryptothrough various operating system security measures, we instead move the cryptoaway from the insecurity. Inother words although the user may be running a system crawling with rogue Active X controls, macroviruses, trojanhorses, and other security night mares, none of the secan come near the crypto.

#### 1.2. Solvingthe Problem

TheFIPS140standardprovidesuswithanumber of guidelinesforthedevelopmentofcryptographic securitymodules.NISToriginallyallowedonly hardwareimplementationsofcryptographicalgorithms (for example the original NISTDES document allowed forhardware implementation only[ 16][17]),however this requirement was relaxed somewhat in the mid-1990'stoallowsoftwareimplementationsaswell [18][19].FIPS140definesfoursecuritylevelsranging fromlevel1(thecryptographicalgorithmsare implementedcorrectly)throughtolevel4(themodule ordevicehasahighdegreeoftamper-resistance includinganactivetamperresponsemechanismwhich causesitto zeroiseitselfwhentamperingisdetected). Todateonlyonegeneral-purposeproductfamilyhas beencertifiedatlevel4[

SinceFIPS140alsoallowsforsoftware implementations, an attempt has been made to provide anequivalentmeasureofsecurityforthesoftware platformonwhichthecryptographicmoduleistorun. Thisisdonebyrequiringtheunderlyingoperating systemtobeevaluatedatprogressivelyhigherOrange BooklevelsforeachFIPS140level,sothatsecurity level2wouldrequirethesoftwaremoduletobe implementedonaC2-ratedoperatingsystem. Unfortunatelythisprovidessomethingifanimpedance mismatchbetweentheactualsecurityofhardwareand softwareimplementations, since it implies that products suchasa Fortezzacard[ 21]orDallas iButton(a relativelyhigh-securitydevice)[ 22]providethesame levelofsecurityasaprogramrunningunderWindows

NT.It's possible that the OS security levels were set so low out of concern that setting the many higher would make it impossible to implement the higher FIPS 140 levels in softwared ue to a lack of systems evaluated at that level.

Evenwithsightssetthislow, it doesn't appear to be possibletoimplementsecuresoftware-onlycryptoona general-purposePC.Tryingtoprotect cryptovariables (ormoregenericallysecurity-relevant dataitems, SRDI'sinFIPS140-speak)onasystemwhichprovides ReadProcessMemoryseems functionslike pointless.evenifthesystemdoesclaimaC2/E2 evaluation.OntheotherhandtryingtosourceaB2or morerealisticallyB3systemtoprovideanadequate levelofsecurityforthecryptosoftwareisalmost impossible(thepracticalityofemployinganOSinthis class, who semembers include Trusted Xenix, XTS300, and Multos, speaks for itself). A simpler solution wouldbetoimplementacryptocoprocessorusinga dedicatedmachinerunningatsystemhigh,andindeed FIPS140explicitlyrecognisesthisbystatingthatthe OSsecurityrequirementsonlyapplyincaseswherethe systemisrunningprogramsotherthanthecrypto module(tocompensateforthis,FIPS140imposesits ownsoftwareevaluationrequirementswhichinsome casesareevenmorearduousthantheOrangeBook ones).

Analternativetoapure-hardwareapproachmightbeto trytoprovidesomeformofsoftware-onlyprotection whichattemptstocompensateforthelackofprotection presentintheOS.Someworkhasbeendoneinthis areainvolvingtheobfuscationofthecodetobe protected, eithermechanically[ 24]. 23]ormanually[ Theuseofmechanicalobfuscation(forexample reoderingofcodeandinsertionofdummyinstructions) isalsopresentinanumberof polymorphic viruses, and canbequiteeffectivelycountered[ 25][26].Manual obfuscationtechniquesaresomewhatmoredifficultto counterautomatically, however computer game vendors havetrainedseveralgenerationsofcrackersintheartof bypassingthemostsophisticatedsoftwareprotection andsecurityfeaturestheycouldcomeupwith [27][28][29],indicatingthatthistypeofprotection won'tprovideanyreliefeither,andthisdoesn'tevengo intotheportabilityandmaintenancenightmarewhich thistypeofcodepresents(itisforthesereasonsthatthe obfuscationprovisionswereremovedfromalater versionoftheCDSAspecificationwheretheywerefirst proposed[30]).

#### 1.3. CoprocessorDesignIssues

Themainconsiderationwhendesigningacoprocessor tomanagecryptooperationsishowmuchfunctionality weshouldmovefromthehostintothecoprocessorunit.

Thebaseline, which we'll callatier <sup>1</sup>0 coprocessor, has all the functionality in the host, which is what we're trying to avoid. The levels above tier 0 provide varying levels of protection for cryptovariables and coprocessor operations, as shown in Figure 1.

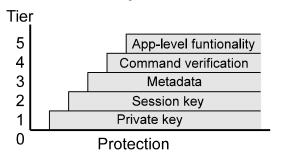

Figure 1:Levelsofprotectionofferedby crypto hardware

Theminimallevelofcoprocessorfunctionality, atier1 coprocessor, moves the private key and private-key operationsoutofthehost. This type of functionality is foundinsmartcards, and is only a small step above havingnoprotectionatall, since although the key itself isheldinthecard, alloperations performed by the card are controlled by the host, leaving the card at the mercy of any malicious software on the host system. In additiontotheseshortcomings, smartcards are very slow, offernoprotection for cryptovariablesotherthan theprivatekey, and often can't even protect the private keyfully(forexampleacardwithanRSAprivatekey intendedforsigningcanbemisusedtodecryptakeyor messagesinceRSAsigninganddecryptionare equivalent).

Thenextleveloffunctionality,tier2,movesboth public/private-keyoperationsandconventional encryptionoperationsalongwithhybridmechanisms suchaspublic-keywrappingofcontent-encryptionkeys intothecoprocessor. This type of functionality is found indevices suchas Fortezzacards and anumber of devices sold as cryptoaccelerators, and provides rather more protection than that found in smart cards since no cryptovariables are ever exposed on the host. Like smart cards however, all control over the devices operation resides in the host, so that even if a malicious application can't get at the keys directly, it can still apply the minamanner other than the intended one.

Thenextleveloffunctionality,tier3,movesallcryptorelated processing (for example certificate generation and message signing and encryption) into the coprocessor. The only control the host has over processingisatthelevelof"signthismessage"or "encryptthismessage", allotheroperations (message formatting, the addition of additional information such asthesigningtimeandsignersidentity, and soon) is performed by the coprocessor. In contrastif the coprocessorhastier1functionalitythehostsoftware canformatthemessageanywayitwants,setthedateto anarbitrarytime(infactitcanneverreallyknowthe truetimesinceit's coming from the system clock which anotherprocesscouldhavealtered), and generally do whateveritwantswithothermessageparameters. Even withatier2coprocessorsuchasa Fortezzacardwhich hasabuilt-inreal-timeclock(RTC),thehostisfreeto ignoretheRTCandgiveasignedmessageany timestampitwants. Similarly, even thoughprotocols likeCSPwhichisusedwith Fortezzaincorporate complexmechanismstohandleauthorisationandaccess controlissues[ 31],theenforcementofthese mechanismsislefttotheuntrustedhostsystemrather thanthecard(!).Otherpotentialproblemareasinvolve handlingofintermediateresultsandcompositecall sequenceswhichshouldn'tbeinterrupted,forexample loadingakeyandthenusingitinacryptographic operation[32].Incontrast, with a tier 3 coprocessor whichperformsallcrypto-relatedprocessing independentofthehostthecoprocessorcontrolsthe messageformattingandtheadditionofadditional inforationsuchasatimestamptakenfromitsown internal clock, moving the mout of reach of any softwarerunningonthehost. The various levels of protectionwhenthecoprocessorisusedformessage decryptionareshownin Figure 2.

Goingbeyondtier3, atier4coprocessor provides facilities such as command verification which prevent the coprocess or from a cting on commands sent from the host system without the approval of the user. The features of this level of functionality are explained in more detail in the section on extended security functionality.

Canwemovethefunctionalitytoanevenhigherlevel, tier5, giving the coprocessor even more control over messagehandling? Althoughit's possible to dothis, it isn'tagoodideasinceatthislevelthecoprocessorwill potentiallyneedtorunmessageviewers(todisplay messages),editors(tocreate/modifymessages),mail software(tosendandreceivethem), and awholehost of other applications, and of course these programs will needtobeabletohandleMIMEattachments,HTML, JavaScript.ActiveX.andsooninordertofunctionas required.Inadditionthecoprocessorwillnowrequire itsowninputmechanism(akeyboard),output mechanism(amonitor), massstorage, and other extras. Atthispointthecoprocessorhasevolvedintoasecond computerattachedtotheoriginalone,andsinceit's runningarangeofuntrustedandpotentiallydangerous

<sup>&</sup>lt;sup>1</sup> Thereasonfortheuseofthissomewhatunusualtermis becausealmosteveryothernounusedtodenotehierarchiesis alreadyinuse;" teir"isunusualenoughthat nooneelsehas gotaroundtousingitintheirsecurityterminology.

codeweneedtothinkaboutmovingthecrypto functionalityintoacoprocessorforsafety.Lather, rinse,repeat.

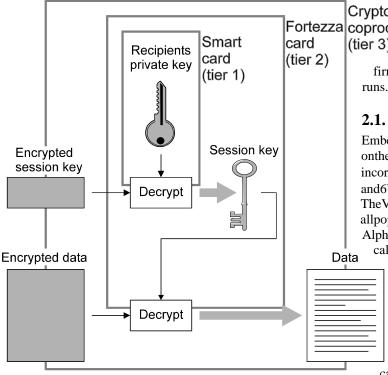

Figure 2:Protectionlevelsforthedecryptoperation

The best level of functionality therefore is to move all crypto and security-related processing into the coprocessor, but to leave everything else on the host.

#### 2. The Coprocessor

Thetraditionalwaytobuildacryptocoprocessorhas beentocreateacompletecustomimplementation, originallywith ASIC's and more recently with a mixtureof ASIC'sandgeneral-purposeCPU's,all controlled by customs of tware. This approach leads to longdesigncycles, difficulties in making changes at a laterpoint, highcosts (with an accompanying strong incentivetokeepalldesigndetailsproprietarydueto theinvestmentinvolved), and reliance on a single vendorfortheproduct.Incontrastanopen-source coprocessorbydefinitiondoesn'tneedtobe proprietary, soit can use existing COTS hardware and softwareaspartofitsdesign, which greatly reduces the cost(thecoprocessordescribedhereisonetotwo ordersofmagnitudecheaperthanproprietarydesigns whileofferinggenerallyequivalentperformanceand superiorfunctionality), and can be sourcedfrom multiplevendorsandeasilymigratedtonewerhardware asthecurrenthardwarebasebecomesobsolete.

The coprocessor requires three layers, the processor hardware, the firmware which manages the hardware (for example initialisation, communications with the

host,persistentstorage,andsoon)andthe

Crypto softwarewhichhandlesthecrypto
coprocessor functionality. Thefollowing
(tier 3) sectionsdescribethecoprocessor
hardwareandresourcemanagement
firmwareonwhichthecryptocontrolsoftware

#### 2.1. CoprocessorHardware

Embeddedsystemshavetraditionallybeenbased ontheVMEbus,a32-bitdata/32-bitaddressbus incorporatedontocardsinthe3U(10 ×16cm) and6U(23 ×16cm) Eurocardformfactor[ 33]. TheVMEbusisCPU-independentandsupports allpopularmicroprocessorsincluding Sparc, Alpha,68K,andx86.Anx86-specificbus calledPC/104,basedonthe104-pinISAbus,

hasbecomepopularinrecentyearsdueto thereadyavailabilityoflow-cost componentsfromthePCindustry.
PC/104cardsaremuchmorecompactat 9×9.5cmthanVMEcards,andunlikea VMEpassive backplane-basedsystem canprovideacompletesystemonasingle card[34].PC/104-Plus,anextensionto

PC/104,addsa120-pinPCIconnectoralongsidethe existingISAone,butisotherwisemostlyidenticalto PC/104[35]

InadditiontoPC/104thereareanumberoffunctionally identical systems with slightly different form factors, of whichthemostcommonisthebiscuitPC,acardthe samesizeasa3½"oroccasionally5¼"drive, witha somewhatlesscommononebeingthecreditcardor SIMMPCroughlythesizeofacreditcard. Abiscuit PCprovidesmostofthefunctionalityandI/O connectorsofastandardPCmotherboard,astheform factorshrinkstheI/Oconnectorsdoaswellsothata SIMMPCtvpicallvusesasingleenormousedge connectorforallitsI/O.Inadditiontotheseform factorstherealsoexistcardPC's(sometimescalledslot PC's), which are biscuit PC's built as ISA or (more rarely)PCI-likecards.Atypicalconfigurationfora low-endsystemisa5x86/133CPU(roughlyequivalent inperformancetoa133MHzPentium),8-16MBof DRAM,2-8MBofflashmemoryemulatingadisk drive, and every imaginable kind of I/O (serial ports, parallelports,floppydisk,IDEharddrive,IRandUSB ports, keyboard and mouse, and others). High-end embeddedsystemsbuiltfromcomponentsdesignedfor laptopuseprovideaboutthesamelevelofperformance asacurrentlaptopPC,althoughtheirpricemakesthem ratherimpractical for use as cryptohardware. To

comparethiswithotherwell-knowntypesofcrypto hardware,atypicalsmartcardhasa5MHz8-bitCPU,a fewhundredbytesofRAM,andafew kBofEEPROM, anda Fortezzacardhasa10or20MHzARMCPU, 64kBofRAMand128kBofflashmemory/EEPROM.

Alloftheembeddedsystemsdescribedaboverepresent COTScomponentsavailablefromalargerangeof vendorsinmanydifferentcountries, witha correspondingrangeofperformanceandpricefigures. Alongsidethex86-basedsystemstherealsoexist systemsbasedonotherCPU's,typicallyARM, Dragonball(embeddedMotorola68K),andtoalesser extentPowerPC,howevertheseareavailablefroma limitednumberofvendorsandcanbequiteexpensive. Besidestheobviousfactorofsystemperformance affectingtheoverallprice,thesmallerformfactorsand useofexotichardwaresuchasnon-generic-PC componentscanalsodriveuptheprice.Ingeneralthe bestprice/performancebalanceisobtainedwithavery genericPC/104orbiscuitPCsystem.

#### 2.2. CoprocessorFirmware

Oncethehardwarehasbeenselectedthenextstepisto determinewhatsoftwaretorunonittocontrolit. The coprocessorisinthiscaseactingasaspecial-purpose computersystemrunningonlythecryptocontrol software, so that what would normally be thought of as theoperating system is acting as the system firmware, andtherealoperatingsystemforthedeviceisthe cryptocontrolsoftware. The controlsoftware therefore representsanapplication-specificoperatingsystem, withcryptoobjectssuchasencryptioncontexts, certificates, and envelopes replacing the user applicationswhicharemanagedbyconventional OS's. The differences between a conventional system and the cryptocoprocessorrunningonetypicaltypeof firmware-equivalentOSareshownin Figure 3.

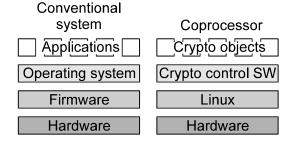

Figure 3:Conventionalsystemvs.coprocessor systemlayers

Sincethehardwareisineffectageneral-purposePC, there'snoneedtouseaspecialised, expensive embeddedorreal-timekernelorOSsinceageneral-purposeOSwillfunctionjustaswell. TheOSchoiceis then something simple like one of the free or nearly-

freeembeddableformsofMSDOS[ 36][37][38]oran opensourceoperatingsystemlikeoneofthex86 BSD's or Linuxwhichcanbeadaptedforuseinembedded hardware. AlthoughembeddedDOSisthesimplestto getgoingandhasthesmallestresourcerequirements, it'sreallyonlyabootstraploaderforreal-mode applicationsandprovidesverylittleaccesstomostof theresourcesprovidedbythehardware. Forthisreason it'snotworthconsideringexceptonextremelylow-end, resource-starvedhardware(it'sstillpossibletofind PC/104cardswith386/40'sonthem, althoughhaving todrivethemwithDOSisprobablyitsown punishment).

AbetterchoicethanDOSisaproperoperatingsystem whichcanfullyutilisethecapabilitiesofthehardware. Theonlyfunctionalitywhichisabsolutelyrequiredof theOSisamemorymanagerandsomeformof communicationwiththeoutsideworld. Alsouseful (althoughnotabsolutelyessential) is the ability to store datasuch as private keys in some form of persistent storage. Finally, the ability to handle multiple threads may be useful where the device is expected to perform multiple cryptotasks at once. A part from the multithreading, the OSisjust acting as a basic resource manager, which is why DOS could be pressed in to use if necessary.

Both FreeBSDand Linuxhavebeenstrippeddownin variouswaysforusewithembeddedhardware[ 39][40]. There's not really alottos avabout the two, both meet therequirements given above, both are open source systems, and both can use a standard full-scale system asthedevelopmentenvironment—whicheveroneis themostconvenientcanbeused.Atthemoment Linux isabetterchoicebecauseitspopularitymeansthere's bettersupportfordevicessuchasflashmemorymass storage(relativelyspeaking,asthe Linuxdriversforthe mostwidely-usedflashdiskareforanoldkernelwhile the FreeBSDonesaremostlyundocumentedandrather minimal), so the coprocessor described here uses Linux asitsresourcemanagementfirmware. Aconvenient featurewhichgivesthefree Unixenanextraadvantage overalternativeslikeembeddedDOSisthatthey'll automaticallyswitchtousingtheserialportfortheir consolesifnovideodriversand/orhardwareare present, which enables them to be used with cheaper embeddedhardwarewhichdoesn'trequireadditional videocircuitryjustfortheone-off setupprocess.A particularadvantageof Linuxisthatit'llhalttheCPU whennothingisgoingon(whichismostofthetime), greatlyreducingcoprocessorpowerconsumptionand heatproblems.

#### 2.3. Firmware Setup

Settingupthecoprocessorfirmwareinvolvescreatinga stripped-down Linux setupcapableofrunningonthe coprocessorhardware. Theservices required of the firmwareare:

- Memorymanagement
- Persistentstorageservices
- Communicationwiththehost
- Processandthreadmanagement(optional)

AllnewerembeddedsystemssupporttheM-Systems DiskOnChip(DOC)flashdisk,whichemulatesa standardIDEharddrivebyidentifyingitselfasaBIOS extensionduringthesysteminitialisationphase (allowing ittoinstall a DOC filesystemdriverto provideBIOS support for the drive) and laters witching toanativedriverfor OS'swhichdon'tusetheBIOSfor hardwareaccess[41]. The first step in installing the firmwareinvolvesformattingtheDOCasastandard harddriveandpartitioningitpriortoinstalling Linux. The DOC is configured to contain two partitions, one mountedread-onlywhichcontainsthefirmwareand cryptocontrolsoftware,andonemountedread/write withadditionalsafetyprecautionslike noexecand nosuid, for storage of configuration information and encryptedkeys.

Thefirmwareconsistsofabasic Linuxkernelwith everyunnecessaryserviceandoptionstrippedout. This means removing support for video devices, mass storage(apartfromtheDOCandfloppydrive), multimediadevices, and other unnecessary bagatelles. ApartfromtheTCP/IPstackneededbythecrypto controls of twareto communicate with the host, there arenonetworkingcomponentsrunning(oreven present)onthesystem,andeventheTCP/IPstackmay beabsentifalternativemeansofcommunicatingwith thehost(explainedinmoredetailfurtheron)are employed. All configuration tasks are performed through consoleaccess via the serial port, and software isinstalledbyconnectingafloppydriveandcopying acrosspre-builtbinaries. This both minimises the size ofthecodebasewhichneedstobeinstalledonthe coprocessor, and eliminates any unnecessary processes andservices which might constitute a security risk. Althoughitwouldbeeasierifweprovidedameansof FTP'ingbinariesacross,thefactthatausermust explicitlyconnectafloppydriveandmountitinorder tochangethefirmwareorcontrolsoftwaremakesit muchhardertoaccidentally(ormaliciously)move problematiccodeacrosstothecoprocessor, provides a work around for the fact that FTP over alternativecoprocessorcommunicationschannelssuchasaparallel portistrickywithoutresortingtotheuseofevenmore

potentialproblemsoftware, and make site asier to comply with the FIPS 140 requirements that (where a non-Orange Book OS is used) it not be possible for extraneous software to be loaded and run on the system. Direct console accessis also used for other operations such as setting the onboard real-time clock, which is used to add time stamps to signatures. Finally, all paging is disabled, both because it isn't needed or safe to perform with the limited-write-cycle flash disk, and because it avoids any risk of sensitive data being written to backing store, eliminating amajor head ache which occurs with all virtual-memory operating systems [42].

Atthispointwehaveabasicsystemconsistingofthe underlyinghardwareandenoughfirmwaretocontrolit andprovidetheserviceswerequire.Runningontopof thiswillbeadaemonwhichimplementsthecrypto controlsoftwarewhichdoestheactualwork.

#### 3. CryptoFunctionalityImplementation

Oncethehardwareandfunctionalitylevelofthe coprocessorhavebeenestablished, we need to design an appropriate programming interface for it. An interface which employs complex data structures, pointers to memory locations, call backfunctions, and other such elements won't work with the coprocessor unless a complex RPC mechanism is employed. Once we get to this level of complexity we run into problems both with lower edperformance due to data marshalling and copying requirements and potential security problems arising from in evitable implementation bugs.

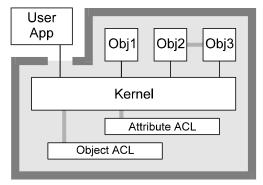

Figure 4:cryptlibarchitecture

Abettertypeofinterfaceistheoneusedinthecryptlib securityarchitecture [43] whichisdepictedin Figure 4. cryptlibimplementsanobject-baseddesignwhich assignsuniquehandlestocrypto-relatedobjectsbut hidesallfurtherobjectdetailsinsidethearchitecture. Objectsarecontrolledthroughmessagessenttothem underthecontrolofacentralsecuritykernel, an interfacewhichisideallysuitedforuseinacoprocessor sinceonlytheobjecthandle(asmallintegervalue) and

oneortwoarguments(eitheranintegervalueorabyte stringandstringlength)areneededtoperformmost operations. This use of only basic parameter types leadstoaverysimpleandlightweightinterface, with onlytheintegervaluesneedingany canonicalisation(to networkbyteorder)beforebeingpassedtothe coprocessor.Acoprocessorcallofthistype,illustrated in Figure 5, requires only a few lines of code more than whatisrequiredforadirectcalltothesamecodeonthe hostsystem.Inpracticetheinterfaceisfurther simplifiedbyusingapre-encodedtemplatecontaining allfixedparameters(forexamplethetypeoffunction callbeingperformedandaparametercount),copyingin anyvariableparameters(forexampletheobjecthandle) withappropriate canonicalistion, and dispatching the resulttothecoprocessor.Thecoprocessorreturns resultsinthesamemanner.

veryeasytounplugtheentirecryptosubsystemand storeitseparatelyfromthehost,movingitoutofreach ofanycovertaccessbyoutsiderswhiletheownerofthe systemisaway.Inadditiontothecarditself,thistype ofstandalone setuprequiresacaseandapowersupply, eitherinternaltothecaseoranexternalwall-warttype (theseareavailableforabout\$10withauniversalinput voltagerangewhichallowsthemtoworkinany country).Thesamearrangementisusedinanumberof commercially-availableproducts,andhastheadvantage thatitinterfacestovirtuallyanytypeofsystem,with thecommensuratedisadvantagethatitrequiresa dedicated ethernetconnectiontothehost(which typicallymeansaddinganextranetworkcard),aswell asaddingtothecluttersurroundingthemachine.

The alternative option for an external coprocessor is to use the parallel port, which doesn't require a network

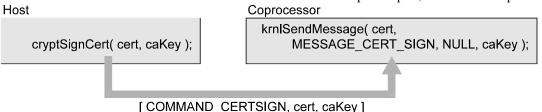

Figure 5: Communicating with the coprocessor

#### 3.1. Communicating with the Coprocessor

Thenextstepafterdesigningtheprogramminginterface istodeterminewhichtypeofcommunicationschannel isbestsuitedtocontrollingthecoprocessor.Sincethe embeddedcontrollerhardwareisintendedfor interfacing to almost anything, there are a widerange of I/Ocapabilities available for communicating with the host.Manyembeddedcontrollersprovidean ethernet interfaceeitherstandardorasanoption, sothemost universalinterfaceusesTCP/IPforcommunications. ForcardPC'swhichplugintothehosts backplanewe should be able to use the system bus forcommunications, and if that isn't possible we can take advantageofthefactthattheparallelportsonallrecent PC'sprovidesophisticated(forwhatwasintendedasa printerport) bidirectionalI/Ocapabilitiesandrunalink from the parallel porton the host mother board to theparallelportonthecoprocessor. Finally, we can use moreexoticI/OcapabilitiessuchasUSBto communicate with the coprocessor.

ThemostuniversalcoprocessorconsistsofabiscuitPC whichcommunicates with the host over ethernet (or, less universally, aparallel port). One advantage which an external, removable coprocessor of this type has over one which plugs directly into the host PC is that it's

cardbutdoestieupaportwhichmayberequiredfor oneofarangeofotherdevicessuchasexternaldisk drives, CDwriters, and scanners which have been kludgedontothisinterfacealongsidethemoreobvious printers. Apartfromits more obvious use, the printer portcanbeusedeitherasanEnhancedParallelPort (EPP)orasanExtendedCapabilityPort(ECP)[ Bothmodesprovideabout1-2MB/sdatathroughput (dependingonwhichvendorsclaimsaretobebelieved) which compares favourably with a parallel port's standardsoftware-intensivemaximumrateofaround 150 kB/sandevenwiththethroughputofa10Mbps ethernetinterface.EPPwasdesignedforgeneralpurpose bidirectionalcommunicationwithperipherals andhandlesintermixedreadandwriteoperationsand blocktransferswithouttoomuchtrouble, whereas ECP (which requires a DMA channel which can complicate thehostsystem'sconfigurationprocess)requires complexdatadirectionnegotiationandhandlingof DMAtransfersinprogress, adding a fair amount of overheadwhenusedwithperipheralswhichemploy mixedreadingandwritingofsmalldataquantities. AnotherdisadvantageofDMAisthatitsuseparalyses theCPUbyseizingcontrolofthebus, halting all threadswhichmaybeexecutingwhiledataisbeing transferred.Becauseofthistheoptimalinterface mechanismisEPP.Fromaprogrammingpointof view.thiscommunicationsmechanismlookslikea permanentvirtualcircuitwhichisfunctionally equivalenttothedumbwirewhichwe'reusingthe

44].

ethernetlinkas, so thetwo can be interchanged with a minimum of coding effort.

Totheuser, the most transparent coprocessor would consistofsomeformofcardPCwhichplugsdirectly intotheirsystem's backplane.Currentlyvirtuallyall cardPC'shaveISAbusinterfaces(thefewwhich supportPCIuseaPCI/ISAhybridwhichwon'tfita standardPCIslot[ 45])whichunfortunatelydoesn't providemuchflexibilityintermsofcommunications capabilitiessincetheonlyviablemeansofmovingdata toandfromthecoprocessorisviaDMA, which requires acustomkernel-modedriveronbothsides. The alternative.usingtheparallelport.ismuchsimpler sincemostoperatingsystemsalreadysupportEPP and/orECPdatatransfers,butcomesattheexpenseofa reduceddatatransferrateandthelossofuseofthe parallelportonthehost. Currently the use of either of theseoptionsisrenderedmootsincetheISAcardPC's assumetheyhavefullcontroloverapassivebackplanebussystem, which means they can't be plugged into a standardPCwhichcontainsitsownCPUwhichisalso assumingthatitsolelycontrolsthebus.It'spossible thatinthefuturecardPC'swhichfunctionasPCIbus devices will appear, but until they doit's not possible to implementthecoprocessorasaplug-incardwithout usingacustomextendercardcontaininganISAorPCI connectorforthehostside,aPC104connectorfora PC104-basedCPUcard, and buffer circuitry in between to isolate the two buses. This destroys the COTS natureof the hardware, limiting availability and raising costs.

The final communication soption uses more exotic I/O capabilities such as USB which are present on newer embedded systems, the searemuch like ethernet but have the disadvantage that they are currently rather poorly supported by most operating systems.

Sincewe'reusing Linuxastheresourcemanagerfor thecoprocessorhardware, we can use a multithreaded implementation of the coprocessors of tware to handle multiples imultaneous requests from the host. After initial is ingthe various cryptlib subsystems, the control software creates a pool of threads which wait on a mutex for commands from the host. When a command arrives, one of the threads is woken up, processes the command, and returns the result to the host. In this manner the coprocessor can have multiple requests outstanding at once, and a process running on the host won't block when ever another process has an outstanding request present on the coprocessor.

#### 3.2. Open vsClosed-sourceCoprocessors

Thereareanumber of vendors who sell various forms of tier 2 coprocessor, all of which run proprietary controls of tware and generally go to some lengths to ensure that no outsiders can ever examine it. The usual

wayinwhichvendorsofproprietaryimplementations trytobuildthesameuserconfidenceintheirproductas wouldbeprovidedbyhavingthesourcecodeand designinformationavailableforpublicscrutinyisto haveitevaluatedbyindependentlabsandtesting facilities, typically to the FIPS 140 standard when the productconstitutescryptohardware(thesecurity implicationsofopensource vsproprietary implementationshavebeencoveredexhaustivelyin various foraandwon'tberepeatedhere). Unfortunatelythisprocessleadstoprohibitively expensiveproducts(thousandstotensofthousandsof dollarsperunit)andstillrequiresuserstotrustthe vendornottoinsertabackdoor,oraccidentallyvoidthe securityviaalatercodeupdateorenhancementadded aftertheevaluationiscomplete(strictlyspeakingsuch post-evaluationchangeswouldvoidtheevaluation,but vendorssometimesforgettomentionthisintheir marketingliterature). Therehave been numerous allegations of the former occurring[ 46][47][48],and occasionalreportsofthelatter.

Incontrast, an open source implementation of the cryptocontrols of tware can be seen to be secure by the enduser with no degree of blind trust required. The user can (if they feel so inclined) obtain the raw coprocess or hardware from the vendor of their choice in the country of their choice, compile the firmware and controls of tware from the open ly-available source code, and installit knowing that no supplemental functionality known only to a few insiders exists. For this reason the entires uite of coprocessor control software is available in source code form for any one to examine, build, and installast hey see fit.

Asecond, farless theoretical advantage of an open-source coprocessor is that until the cryptocontrol code is loaded into it, it is n't a control led cryptographic item as cryptosource code and software aren't control led in most of the world. This means that it's possible to ship the hardware and software separately to almost any destination (or source it locally) without any restrictions and then combine the two to create a control led item once they arrive at their destination (like at wo-component glue, things don't get stick yuntily ou mix the parts).

#### 4. ExtendedSecurityFunctionality

Thebasiccoprocessordesignpresentedsofarservesto moveallsecurity-relatedprocessingand cryptovariablesoutofreachofhostilesoftware, butby takingadvantageofthecapabilitiesofthehardwareand firmwareusedtoimplementit, it's possible to domuch more. One of the features of the cryptlibarchitecture is that alloperations are controlled and monitored by a central security kernel which enforces a single,

consistentsecuritypolicyacrosstheentirearchitecture. Bytyingthecontrolofsomeoftheseoperationsto featuresofthecoprocessor,it'spossibletoobtainan extendedlevelofcontroloveritsoperationaswellas avoidingsomeoftheproblemswhichhavetraditionally plaguedthistypeofsecuritydevice.

#### 4.1. ControllingCoprocessorActions

Themostimportanttypeofextrafunctionalitywhich canbeaddedtothecoprocessorisextendedfailsafe controloveranyactionsitperforms. This means that insteadofblindlyperforminganyactionrequestedby thehost(purportedlyonbehalfoftheuser), it first seeks confirmationfromtheuserthattheyhaveindeed requestedthattheactionbetaken.Themostobvious application of this mechanism is for signing documents wheretheownerhastoindicatetheirconsentthrougha trustedI/Opathratherthanallowingarogueapplication torequestarbitrarynumbersofsignaturesonarbitrary documents. This contrasts withother tier 1 and 2 processorswhicharetypicallyenabledthroughuser entryofaPINorpassword,afterwhichtheyareatthe mercyofanycommandscomingfromthehost.Apart from the security concerns, the ability to individually controlsigningactionsandrequireconsciousconsent fromtheusermeansthatthecoprocessorprovidesa mechanismrequiredbyanumberofnewdigital signaturelawswhichrecognisethedangersinherentin systemswhichprovideanautomated(thatis, with little controlfromtheuser)signingcapability.

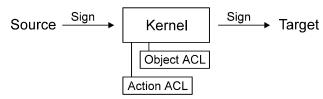

Figure 6:Normalmessageprocessing

Themeansofprovidingthisserviceistohookintothe cryptlibkernel'ssignactionanddecryptaction processing mechanisms. Innormal processing the kernelreceivestheincomingmessage, applies various security-policy-related checks to it (for example it checkstoensurethattheobject's ACL allows this type ofaccess), and then forwards the message to the intendedtarget, as shown in Figure 6. In order to obtain additional confirmation that the action is to be taken, thecoprocessorcanindicatetherequestedactiontothe userandrequestadditionalconfirmationbeforepassing themessageon. If the user chooses to denyther equest ordoesn'trespondwithinacertaintime, therequest is blockedbythekernelinthesamemannerasifthe objectsACLdidn'tallowit,asshownin Figure 7.This mechanismissimilartothecommandconfirmation

mechanisminthe VAXA1 security kernel, which takes a command from the untrusted VMS or Ultrix-32 OS's running on top of it, requests that the user press the (non-overridable) secure attention key to communicate directly with the kernel and confirm the operation ("Something claiming to be you has requested X. Is this OK?"), and then returns the user back to the OS after performing the operation [49].

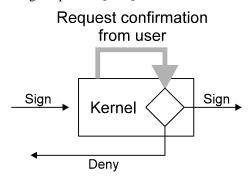

Figure 7:Processingwithuserconfirmation

ThesimplestformofuserinterfaceinvolvestwoLED's andtwopushbuttonswitchesconnectedtoasuitable portonthecoprocessor(forexampletheparallelportor serialportstatuslines). AnLEDisactivatedtoindicate that confirmation of a signing or decryption action is required by the coprocessor. If the user pushes the confirmation button, the requestis allowed through, if they push the cancel button or don't respond within a certain time, the request is denied.

#### 4.2. TrustedI/OPath

Thebasicuserconfirmationmechanismpresented abovecanbegeneralisedbytakingadvantageofthe potential for a trusted I/O pathwhich is provided by the coprocessor. The mainuse for a trusted I/O pathisto allowforsecureentryofapasswordorPINusedto enableaccesstokeysstoredinthecoprocessor.Unlike typicaltier1deviceswhichassumetheentiredeviceis secureanduseashortPINincombinationwitharetry countertoprotect cryptovariables, the coprocessor makesnoassumptionsaboutitssecurityandinstead reliesonauser-suppliedpasswordtoencryptall cryptovariablesheldinpersistentstorage(theonlytime keysexistin plaintextformiswhenthey'redecrypted tovolatilememorypriortouse). Because of this, a simplenumerickeypadusedtoenteraPINisn't sufficient(unlesstheuserenjoysmemorisinglong stringsofdigitsforuseaspasswords). Instead, the coprocessorcanoptionallymakeuseofdevicessuchas PalmPilotsforpasswordentry,perhapsincombination withnovelpasswordentrytechniquessuchasgraphical passwords[50].Notethoughthat,unlikeatier0crypto implementation, obtaining the userpass word via a keyboard snifferonthehostdoesn'tgiveaccessto

privatekeyssincethey'reheldonthecoprocessorand canneverleaveit,sothatevenifthepasswordis compromisedbysoftwareonthehost,itwon'tprovide accesstothekeys.

Inaslightlymoreextremeform, the ability to access thecoprocessorviamultipleI/Ochannelsallowsusto enforcestrictred/blackseparation,with plaintextbeing accessedthroughoneI/Ochannel, ciphertextthrough another, and keysthrough at hird. Although cryptlib doesn'tnormallyload plaintextkeys(they'regenerated andmanagedinternallyandcanneverpassoutsidethe securityperimeter), when the ability to load external kevsisrequiredFIPS140mandatesthatthevbeloaded viaaseparatechannelratherthanovertheoneusedfor generaldata, which can be provided for by loading themoveraseparatechannelsuchasaserialport(a number of commercial cryptocoprocessors come with a serialportforthisreason).

#### 4.3. PhysicallyIsolatedCrypto

Ithasbeensaidthattheonlytrulytamperproof computerhardwareisVoyager2,sinceithasa considerableairgap(strictlyspeakinganon-airgap) whichmakesaccesstothehardwaresomewhat challenging(spacealiensnotwithstanding). Wecan takeadvantageofair-gapsecurityincombinationwith cryptlib's remote-execution capability by siting the hardwareperformingthecryptoinasafelocationwell awayfromanypossibletampering.Forexampleby runningthecryptoonaserverinaphysicallysecure locationand tunnelingdataandcontrolinformationtoit viaitsbuilt-in sshorSSLcapabilities, we obtain the benefitsofphysicalsecurityforthecryptowithoutthe awkwardnessofhavingtouseitfromasecurelocation ortheexpenseofhavingtouseaphysicallysecure cryptomodule(theimplicationsofremoteexecutionof cryptofromacountrylikeChinawithkeysandcrypto heldinEuropeortheUSareleftasanexerciseforthe reader).

Physicalisolationatthemacroscopiclevelisalso possibleduetothefactthatcryptlibemploysa separationkernelforitssecurity[ 51][52],whichallows differentobjecttypes(and,atthemostextremelevel, individualobjects)tobeimplementedinphysically separatehardware.Forthoserequiringanextremelevel ofisolationandsecurity, its hould be possible to implementthedifferentobjecttypesintheirown keysetobjects(whichdon't hardware, for example requireanyrealsecuritysincecertificatescontaintheir owntamperprotection)couldbeimplementedonthe hostPC,thekernel(whichrequiresaminimumof resources)couldbeimplementedonacheapARMbasedplug-incard, envelopeobjects (which can require afairbitofmemorybutverylittleprocessingpower)

couldbeimplementedona486cardwithagood quantityofmemory,andencryptioncontexts(which canrequireafairamountofCPUpowerbutlittleelse) couldbeimplementedusingafasterPentium-class CPU.Inpracticethoughit'sunlikelythatanyone wouldconsiderthislevelofisolationworththeexpense andeffort.

#### 5. CryptoHardwareAcceleration

Sofarthediscussionofthecoprocessorhasfocusedon these curity and functionality enhancement sit provides, avoiding anymention of performance concerns. The reasonforthisisthatforthemajorityofusersthe performanceisgoodenough, meaning that for typical applications such as emailencryption, webbrowsing withSSL.andremoteaccessvia ssh.thepresenceofthe coprocessorisbarelynoticeablesincethelimiting factorsonperformancearesetbynetworkbandwidth, diskaccesstimes, modem speed, bloatwarerunningon thehostsystem,andsoon.Althoughneverintended foruseasaspecial-purposecryptoacceleratorofthe typecapableofperforminghundredsofRSAoperations persecondonbehalfofaheavily-loadedwebserver,it ispossibletoaddextrafunctionalitytothecoprocessor throughitsbuilt-inPC104bustoextendits performance.ByaddingaPC104 daughterboardtothe device, it's possible to enhance its functionality or add newfunctionalityinavarietyofways, as explained below(althoughthepricesquotedfordeviceswill changeovertime, the price ratios should remain relativelyconstant).

#### 5.1. ConventionalEncryption/Hashing

ImplementinganalgorithmlikeDESwhichwas originallytargetedathardwareimplementation.ina field-programmablegatearray(FPGA)isrelatively straightforward,andhashalgorithmslikeMD5and SHA-1canalsobeimplementedfairlyeasilyin hardwarebyimplementingasingleroundofthe algorithmandcyclingthedatathroughitthe appropriatenumberoftimes. Using alow-cost FPGA, itshouldbepossibletobuilda daughterboardwhich performsDESandMD5/SHA-1accelerationforaround \$50.Unfortunately,anumberofhardwareandsoftware issuesconspiretomakethisnon-viableeconomically. ThemainproblemisthatalthoughDESisfasterto implementinhardwarethaninsoftware, mostnewer algorithmsaremuchmoreefficientinsoftware(ones withlarge, key-dependent S-boxes are particularly difficulttoimplementin FPGA'sbecausetheyrequire hugenumbersoflogiccells, requiring very expensive high-density FPGA's). Arelated problemist hefact thatinmanycasestheCPUonthecoprocessoris alreadycapableofsaturatingtheI/Ochannel (ethernet/ECP/EPP/PC104)usingapuresoftware

implementation, sothere's nothing to be gained by adding expensive external hardware (all of the software-optimised algorithms runats everal MB/s whereas the I/O channel is only capable of handling around 1 MB/s). The imbalance becomes even worse when any CPU faster than the entry-level 5x86/133 configuration is used, since at this point any common algorithm (even the rathers low triple DES) can be executed more quickly in software than the I/O channel can handle. Because of this it doesn't seem profitable to try to augments of tware-based conventional encryption or hashing capabilities with extra hardware.

#### 5.2. Public-keyEncryption

Public-keyalgorithmsarelessamenableto implementationingeneral-purposeCPU'sthan conventional encryption and hashing algorithms, sothere'smorescopeforhardwareaccelerationinthis area. Wehavetwooptions for accelerating public-key operations, either using an ASIC from a vendor or implementingourownversionwithanFPGA. **Bignum** ASIC's are somewhat thin on the ground since the vendorswhoproducethemusuallyusethemintheir owncryptoproductsanddon'tmakethemavailablefor saletothepublic, however there is one company who specialisein ASIC'sratherthancryptoproductswho cansupplya bignumASIC(it'salsopossibletolicense bignumcoresandimplementthedeviceyourself,this optioniscoveredperipherallyinthenextsection). Usingthisdevice,thePCC201[ 53],it'spossibleto builda bignumacceleration daughterboardforaround \$100.

Unfortunately, the device has a number of limitations. Althoughimpressive when it was first introduced, the maximumkeysizeof1024bitsandmaximum throughputof21operations/sfor1024-bitkeysand74 operations/sfor512-bitkeyscomparesratherpoorly withsoftwareimplementationsonnewerPentium-class CPU's, which can achieve the same performance with a CPUspeedofaround200MHz.Thismeansthat althoughoneofthesedeviceswouldservetoaccelerate performanceonacoprocessorbasedontheentry-level 5x86/133hardware, abetterway to utilise the extra expenseofthe daughterboardwouldbetobuythenext levelupincoprocessorhardware, giving somewhat better bignumperformanceandacceleratingallother operations as well as a free side-effect (the entry level forPentium-classcardsisonecontaininga266MHz Cyrix MediaGX, although it may be possible to put togetheranevencheaperoneusingabarecardand populatingitwithanAMDK6/266, currently selling for around \$30). A second disadvantage of the PCC 201 isthatit'smadeavailableunderpeculiarexportcontrol termswhichcanmakeitcumbersome(oreven

impossible)toobtainforanyonewhoisn'talarge company.

AnalternativetousinganASICistoimplementour own bignumacceleratorwithanFPGA, with the advantagethatwecanmakeitasfastasrequired (withinthelimitsoftheavailablehardware). Again, thereistheproblemthatmuchofthepublishedworkin bignumacceleratordesignisbycrypto theareaof hardwarevendorswhodon'tmakethedetailsavailable, howeverthereisonereasonablyfastimplementation whichachieves83operations/sfor1024-bitkeysand 340operations/sfor512-bitkeysusingatotalof6,700 FPGAbasiccells(configurablelogicblocksor CLB's) [54]. Theuse of such a large number of CLB'srequires theuseofveryhigh-density FPGA's, of which the most widely-usedrepresentativeisthe XilinxXC4000family [55]. The cheapest available FPGA capable of implementingthisdesign,theXC40200,comeswitha pre-printedmortgageapplicationformanda\$2000-\$2500pricetag(dependingonspeedgradeand quantity), providing a clue as to why the design has to dateonlybeenimplementedonasimulator. Again, it's possibletobuyanawfullotofCPUpowerforthesame amountofmoney(anequivalentlevelofperformance totheFPGAdesignisobtainableusingabout\$200 worthofAMD AthlonCPU[ 56]).

Thisillustratesaproblemfacedbyallhardwarecrypto acceleratorvendors, whichmay be stated as a derivation of Moore's law: Intelcan make it faster cheaper than you can. In other words, putting a lot of effort into designing an ASIC for a crypto accelerator is a risky investment because, as ide from the usual flexibility problems caused by the use of an ASIC, it'll be rendered obsolete by general-purpose CPU's within a few years. This problem is demonstrated by several products currently sold as cryptohardware accelerators which in fact act as cryptohard brakes since, when plugged in orenabled, performance slows down.

Forpureaccelerationpurposes, the optimal price/performance tradeoffappearstobetopopulatea daughterboardwithacollectionofcheapCPU's attachedtoasmallamountofmemoryandjustenough gluelogictosupporttheCPU(thisapproachisusedby nCipher,whouseaclusterofARMCPU'sintheirSSL accelerators [57]). The mode of operation of this CPU farmwouldbeforthecryptocoprocessortohaltthe CPU's, load the control firmware (abasic protectedmodekernelandappropriatecodetoimplementthe required bignumoperation(s))intothememory,and restarttheCPUrunningasaspecial-purpose bignum engine.Forx86CPU's,thereareanumberofvery minimalopen-sourceprotected-modekernelswhich wereoriginallydesignedasDOSextendersforgames programming available, these ignorevirtual memory,

pageprotection, and other issues and run the CPU as if it were very fast a 32-bit real-mode 8086. By using a processor like a K6-23 D/333 (currently selling for around \$35) which contains 32+32 Ko fon board cache, the control code can be loaded initially from slow, cheap external memory but will execute from cache at the full CPU speed from the non. Each of the sededicated big numunits should be capable of ~200512-bit RSA operations per second at a cost of around \$100 each.

Unfortunatelytheuseofcommodityx86CPU'softhis kindhasseveraldisadvantages. The first is that they aredesignedforuseinsystemswithacertainfixed configuration(forexampleSDRAM,PCIandAGP busses, a64-bitbusinterface, and other highperformanceoptions) which means that using them with asinglecheap8-bitmemorychiprequiresafairamount ofgluelogictofakeoutthecontrolsignalsfromthe externalcircuitrywhichisexpectedtobepresent. The second problem is that these CPU's consume significantamountsofpoweranddissipatealargeamountofheat, withcurrentdrainsof10-15Aanddissipationsof20-40Wbeingcommonfortherangeoflow-end processorswhichmightbeusedascheapaccelerator engines.AddingmoreCPU'stoimproveperformance onlyservestoexacerbatethisproblem, since the power suppliesandenclosuresdesignedforembedded controllersarecompletelyoverwhelmedbythe requirementsofaclusteroftheseCPU's.Althoughthe low-costprocessingpowerofferedbygeneral-purpose CPU'sappearstomakethemidealforthissituation,the practicalproblemstheypresentrulesthemoutasa solution.

Afinalalternativeisofferedbydigitalsignalprocessors (DSP's), which require virtually no external circuitry sincemostneweronescontainenoughonboardmemory toholdalldataandcontrolcode,anddon'texpectto findsophisticated external controllogic present. The factthat DSP's are optimised for embedded signalprocessingtasksmakesthemidealforuseas bignum accelerators, since a typical configuration contains two 32-bitsingle-cyclemultiply-accumulate(MAC)units whichprovideinoneinstructionthemostcommon basicoperationusedin bignumcalculations. Thebest DSPchoiceappearstobetheADSP-21160, which consumes only 2 watts and contains built-in multiprocessorsupportallowingupto6 DSP'stobe combinedintoonecluster[ 58]. The aggregate 3,600 MFLOPSprocessingpowerprovidedbyoneofthese clustersshouldprovesufficient(initsinteger bignumcalculations. The equivalent)toaccelerate feasibilityofusing DSP'saslow-costacceleratorsis currentlyunderconsiderationandmaybethesubjectof afuturepaper.

#### **5.3. Other Functionality**

Inadditiontopureaccelerationpurposes, it's possible tousea PC 104 add-oncard to handle an umber of other functions. The most important of these is a hardware random number generator (RNG), since the effectiveness of the standard entropy-polling RNG using by cryptlib [59] is somewhat impaired by its use in a nembed dedenvironment. A typical RNG would take advantage of several physical randomness sources (typically thermal noise in semiconductor junctions) fed into a Schmitt rigger with the output mixed into the standard cryptlib RNG. The use of multiple independent sources ensures that even if one fails the others will still provide entropy, and feeding the RNG output into the cryptlib PRNG ensures that any possible biasis removed from the RNG output bits.

AsecondfunctionwhichcanbeperformedbytheaddoncardistoactasamoregeneralI/Ochannelthanthe basicLED-and-pushbuttoninterfacedescribedearlier, providingtheuserwithmoreinformation(perhapsvia anLCDdisplay)onwhatitisthey'reauthorising.

#### 6. Conclusion

Thispaperhaspresentedadesignforaninexpensive, general-purposecryptocoprocessorcapableofkeeping cryptokeysandcryptoprocessingoperationssafeeven inthepresenceofmalicioussoftwareonthehostwhich itiscontrolledfrom.Extendedsecurityfunctionalityis providedbytakingadvantageofthepresenceoftrusted I/Ochannelstothecoprocessor.Althoughsufficient formostpurposes, the coprocessors processing power maybeaugmentedthroughtheadditionofadditional DSP'swhichshouldbringthe modulesbasedon performanceintolinewithconsiderablymoreexpensive commercialequivalents. Finally, the open-source natureofthedesignanduseofCOTScomponents meansthatanyonecaneasilyreassurethemselvesofthe securityoftheimplementationandcanobtaina coprocessorinanyrequiredlocationbyrefrainingfrom combiningthehardwareandsoftwarecomponentsuntil they'reattheirfinaldestination.
