

# Write Amplification Reduction in Flash-Based SSDs Through Extent-Based Temperature Identification

Mansour Shafaei Peter Desnoyers Jim Fitzpatrick

**SanDisk®**

# Outline

---

- ▶ Background
- ▶ Related Work
- ▶ Extent-Based Temperature Identification
  - ▶ Evaluations
- ▶ Conclusion

# Background

---

- ▶ Performance of flash-based storage dominated by
  - ▶ Cleaning costs (Write Amplification)
    - ▶ The number of internal copies required before erasing blocks
- ▶ WA reduction
  - ▶ Selection (Non-predictive)
    - ▶ Cost-Benefit based block selection
  - ▶ Placement (Predictive)
    - ▶ Hot/Cold data segregation
      - High performance
      - Requires write frequency/recency tracking

# Data Temperature Identification Schemes

---

- ▶ **Implicit**

- ▶ Length heuristic

- ▶ Short host writes → shorter-lived data
      - Inaccuracy issues

- ▶ **Explicit**

- ▶ Per LBA data access tracking

- ▶ EWMA
      - Requiring excessive resources

- ▶ Approximated

- ▶ E.g., Multiple Hash Functions (MHF) (Hsieh et al.) and Multiple Bloom Filters (MBFs) (Park et al.)

# Density-based clustering

---

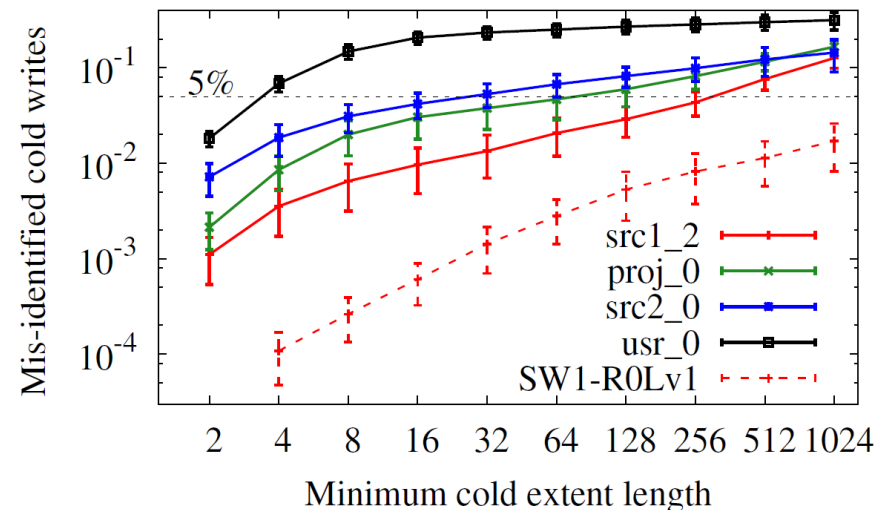

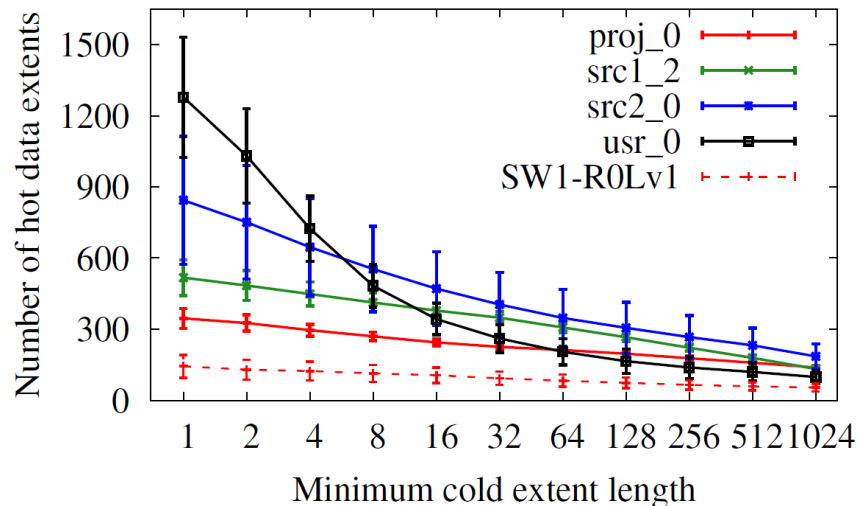

- ▶ Data temperature identification can be considered as a density-based stream clustering problem
  - ▶ Well-studied subject in the AI domain
- ▶ Definition
  - ▶ Finding arbitrary shape clusters based on the density of data in a given address space
    - Forming dense clusters separated by sparse areas

## ▶ Types

# Applicability of Density-Based Clustering to Storage Workloads

- ▶ Running trace driven test to measure:
  - ▶ Number of extents needed for accurate identification
  - ▶ Accuracy loss by merging hot extents separated by small amounts of cold data

# Extent-Based Temperature Identification (ETI)

- ▶ Beginning with a single extent covering the entire address space

- ▶ Extent and counter updates based on incoming writes
  - ▶ If boundaries of corresponding extent match incoming write's offset and length:

- ▶ Increments the counter

- ▶ Otherwise, if # of extents < max. # of allowed extents:
    - ▶ Creates new extents accordingly and increments the counter values

- ▶ Else:

- ▶ Increments the extent counters fully or partially (>  $\alpha\%$ ) overwritten by the write

## ETI (cont.)

---

- ▶ **Periodic aging**
  - ▶ Divide all counters by two and round off
  - ▶ Merge all adjacent hot extents with equal counter values
  - ▶ Merge all adjacent cold (counter  $< \beta$ ) extents

# ETI Overhead

---

- ▶ More complex
  - ▶ Requiring an ordered search structure vs. Bloom filter
- ▶ Per write operation execution
  - ▶ Vs. existing scheme's per block operations
  - ▶ Up to 96% reduction among available traces
- ▶ Optimized search by taking advantage of spatial locality
  - ▶ Beginning each search at the location of latest accessed extent

# Experimental Setup

---

- ▶ Environment

- ▶ FTLSim

- A high-level SSD simulator written in C and Python

- ▶ Page-map FTL

- ▶ 32K of 128-page blocks ~ 16 GB

- ▶ 7% spare factor

- ▶ A global greedy cleaning algorithm with hot and cold data segregation

- ▶ Metric

- Write Amplification

# Experimental Setup (Cont.)

---

## ▶ Schemes

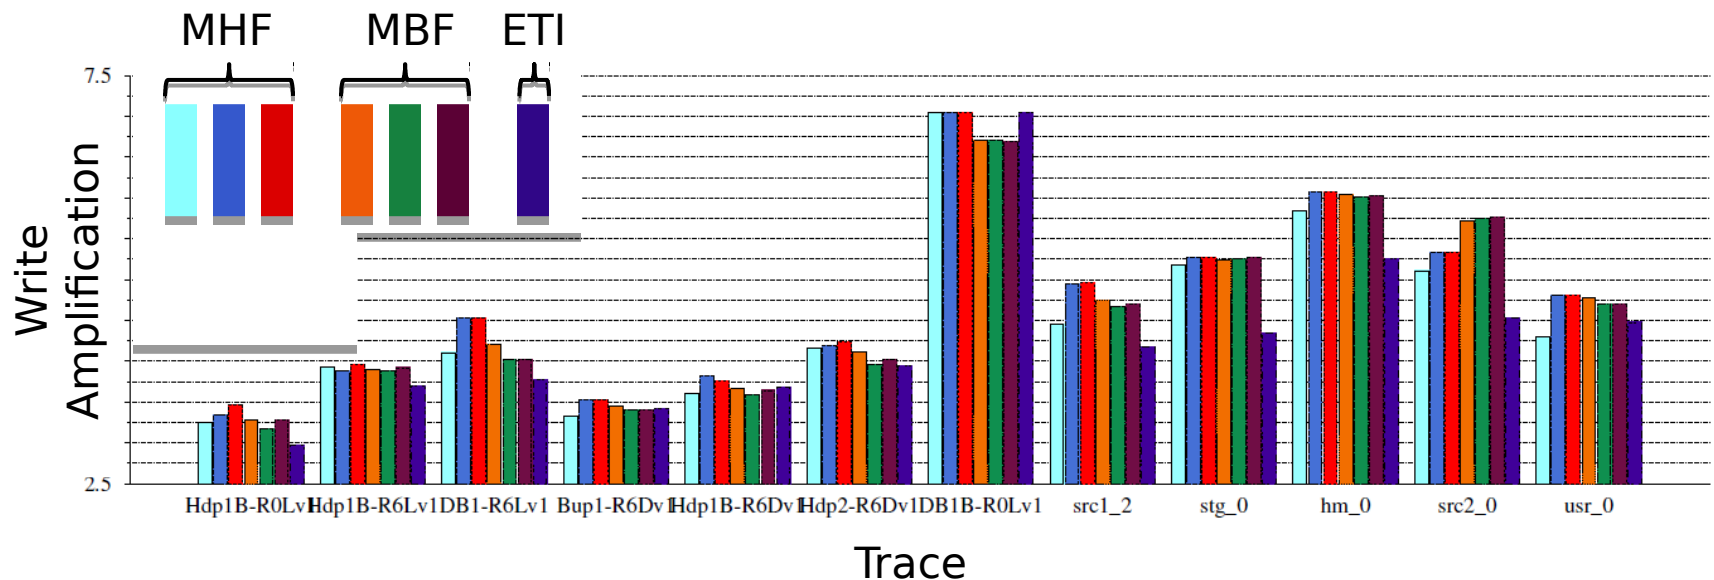

- ▶ ETI (max. # of extents=2048)
- ▶ MHF (table size=2048, CRC HFs)
- ▶ MBF (BF size=2048, CRC HFs)

## ▶ Workload

- ▶ Selected MSR traces
- ▶ A series of traces provided by an industrial partner
  - ▶ One RAID-0 and two RAID-6 variants
  - ▶ Two backup applications, a database, a Hadoop HDFS cluster, and an unspecified software application

# Performance Comparison

- ▶ Using ETI
  - ▶ Up to 21% WA reduction
  - ▶ Never worse than MHF
  - ▶ Only 4% worse in one single trace compared to MBF

# Performance Comparison (cont.)

- ▶ Dedicating more memory resources to the implemented hash-based schemes for a more fair comparison
  - ▶ MBFs with twice and 4 times larger BF sizes
  - ▶ Modest improvements in four traces
    - ▶ Significantly less than what achieved by ETI
  - ▶ Almost no improvement in two other traces!

# Conclusion

---

- ▶ We propose Extent-based Temperature Identification (ETI) as a one-dimensional density-based clustering scheme to get used combined with a dual frontier, page-mapped Greedy translation layer.
- ▶ We measure by write amplification reduction unlike previous work which used identification accuracy.
- ▶ Results show by up to 21% WA reductions over both Multiple Hash Functions and Multiple Bloom Filters schemes.
