

The making of an  
**Ultra Low Latency Trading System**  
With Java and Golang

Yucong Sun  
Staff Software Engineer

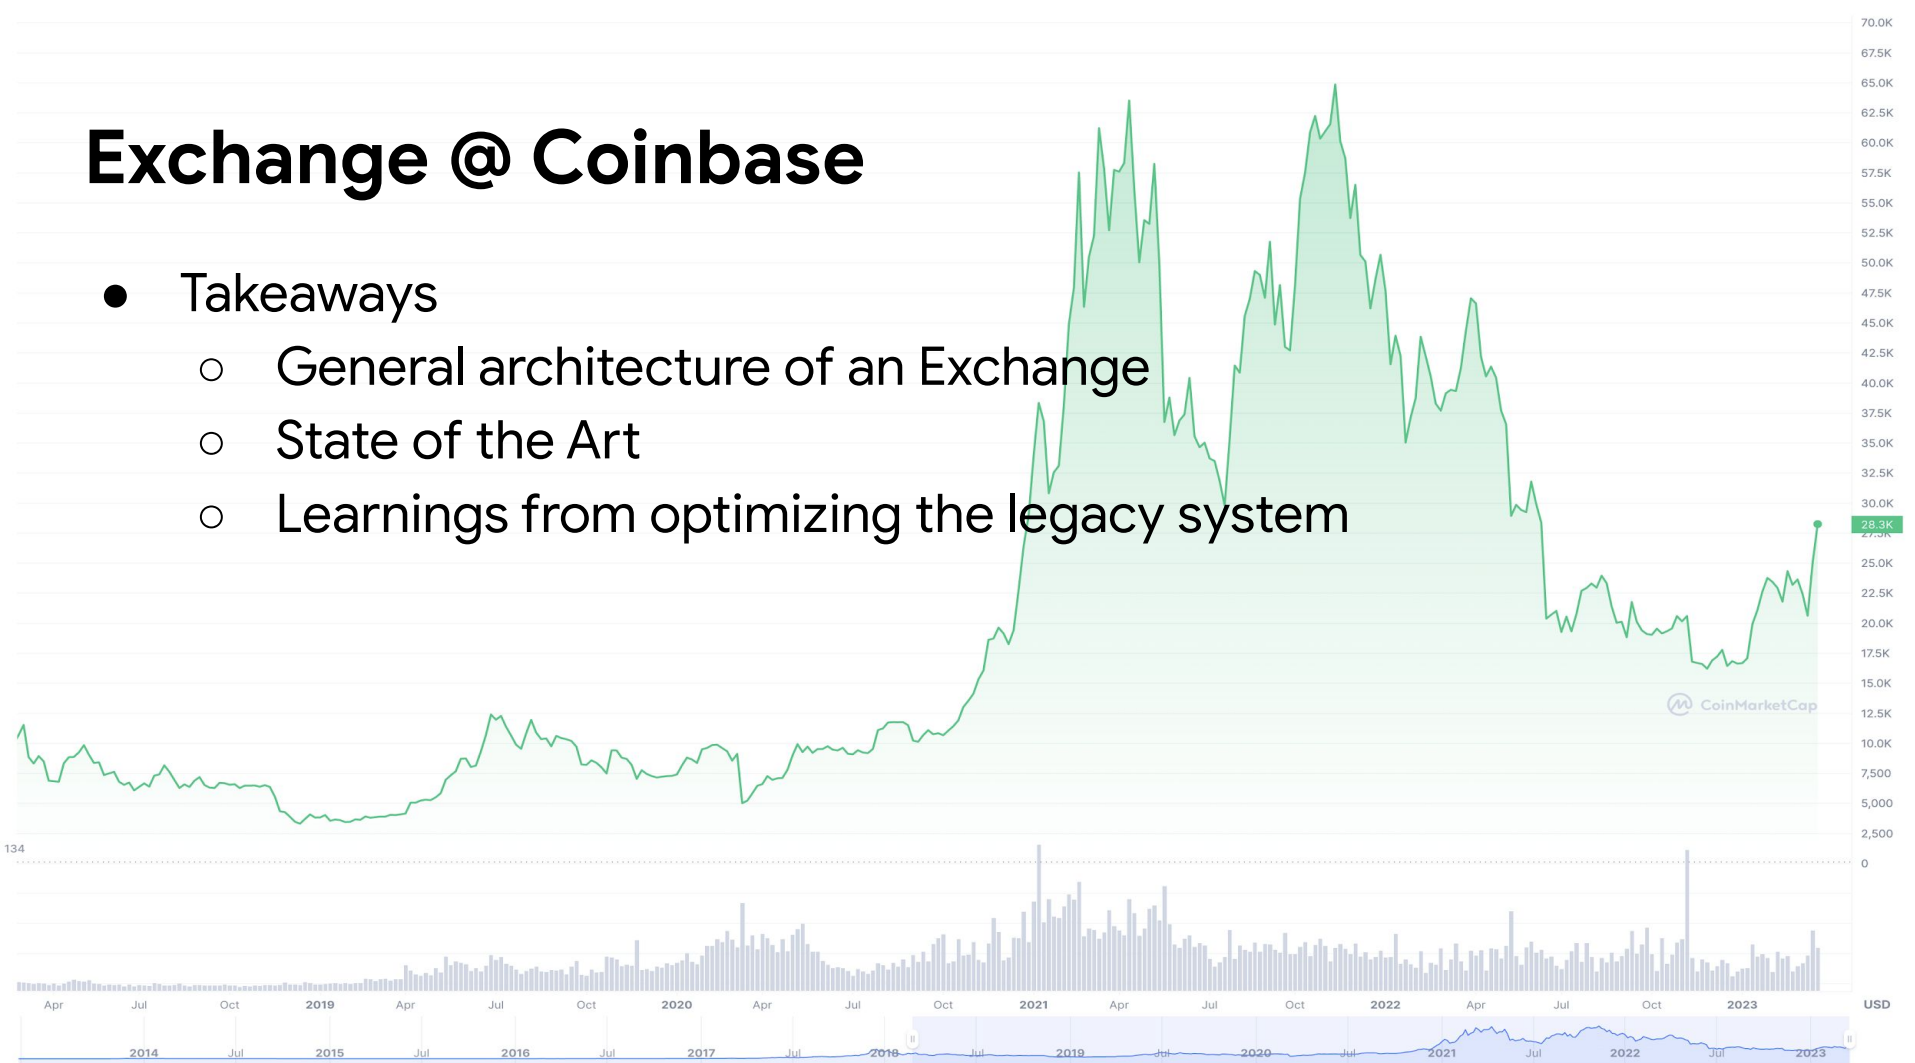

Jonathan Ting  
Senior Software Engineer

# Exchange @ Coinbase

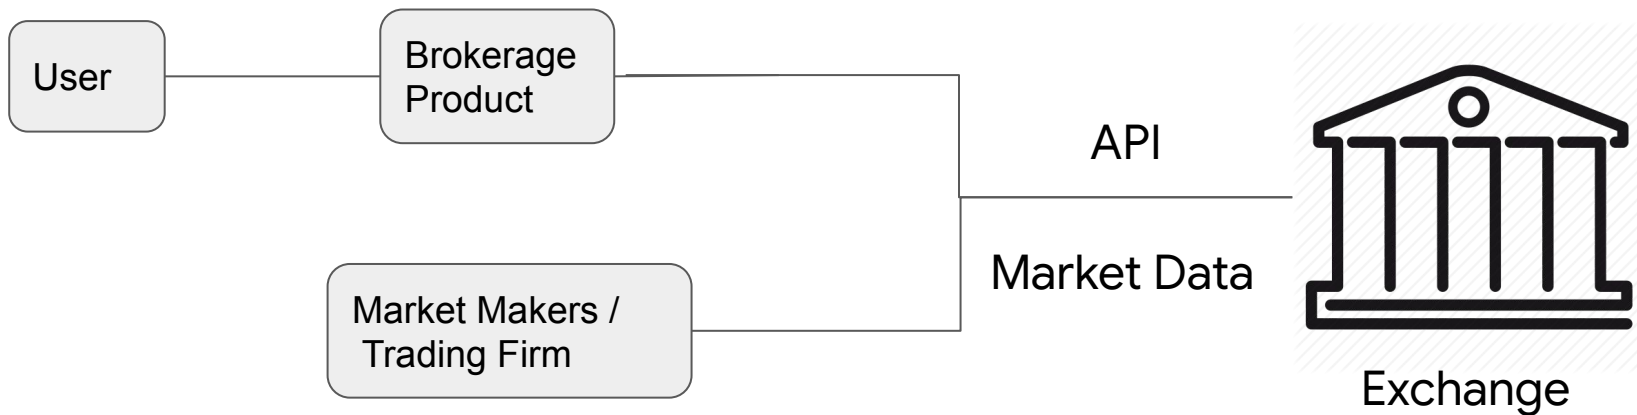

- Takeaways

- General architecture of an Exchange
- State of the Art
- Learnings from optimizing the legacy system

# Planetary view of an Exchange

Most users would/should not interact with an Exchange directly

# Orbital view of an Exchange

## Order Management System:

Balance, Risk, Margin/Liquidations

## Matching Engine: Order book

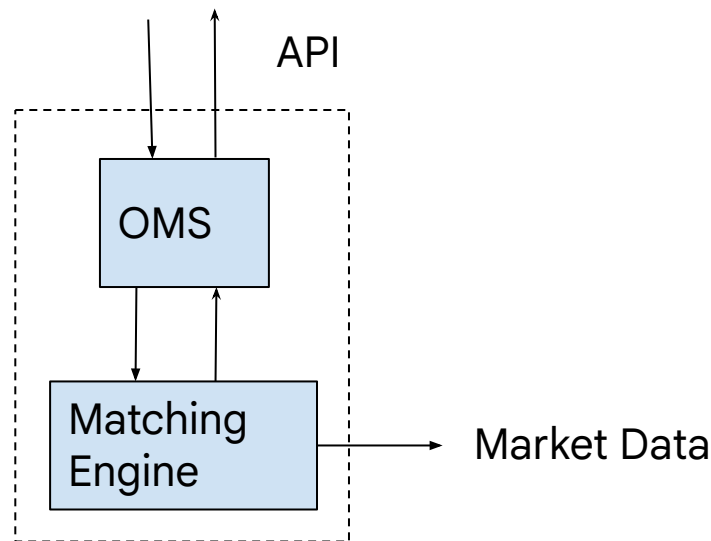

**API:** FIX, HTTP

**MarketData:** FIX, Websocket

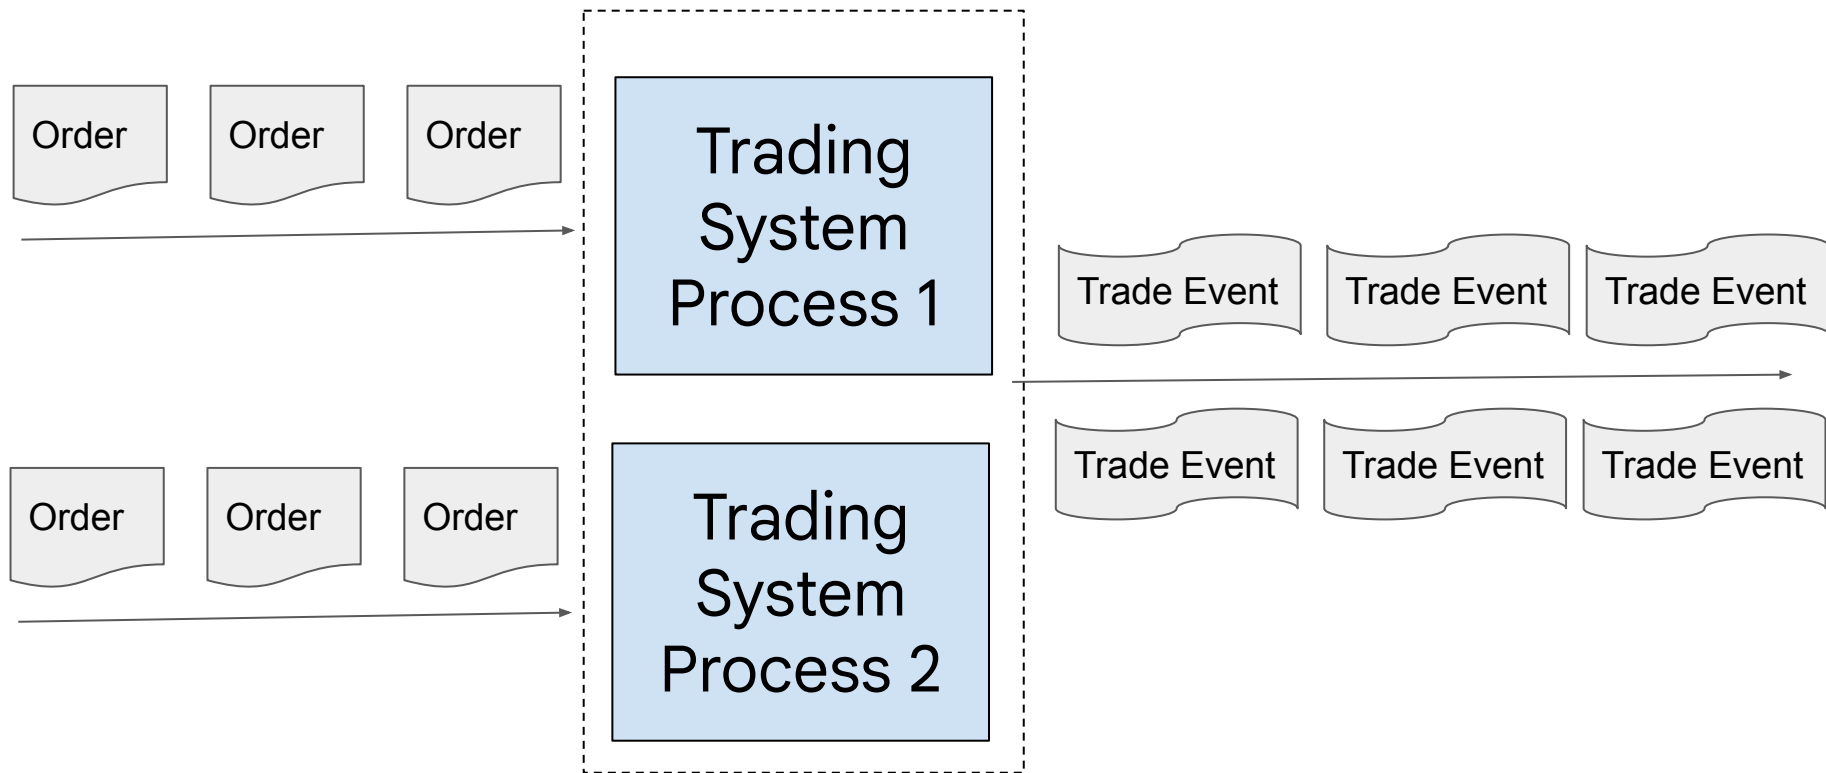

**Hot path:** Balance check, Order Matching

**Warm path:** Settlement

**Auxiliary:** Market Data Feed

# Assembly Lines of a Exchange

**Exhibit A:**

# **Coinbase Derivatives Exchange**

<https://www.coinbase.com/derivatives>

# Trading System Logic Isn't Complex

Hot Path

Submit & match incoming orders against resting orders ('book')

Public - no complex trading relationships

Other logic (timers, admin requests, state)

Affect trading logic, so want to be sequenced with any other events

Trading system assigns IDs to state

Single threaded

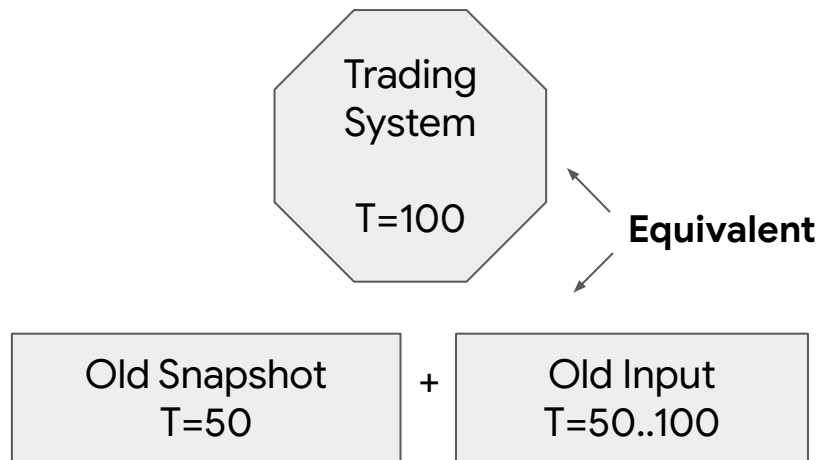

## Trading System as **Deterministic State Machine**

State<sub>0</sub> + Input<sub>0</sub> => State<sub>1</sub> + Output<sub>1</sub> **ALWAYS**

Can snapshot/restore/replay to get to live state

Determinism is Tricky!

- Data Structure Iteration
- No randomness
- Behavior changes
  - Old input => Old behavior
  - Feature flagging

# Fault Tolerance with RAFT

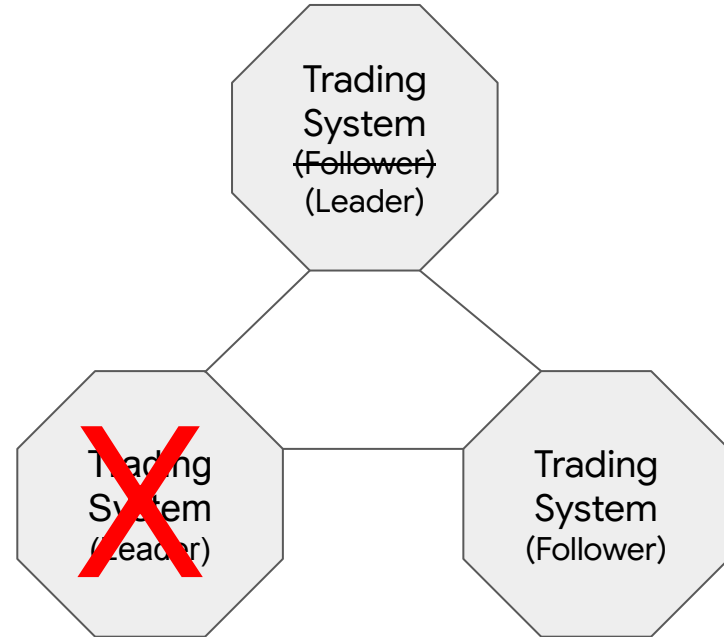

## Aeron Cluster

High performance RAFT implementation

App has to be deterministic & single threaded

Consensus batched & pipelined with application

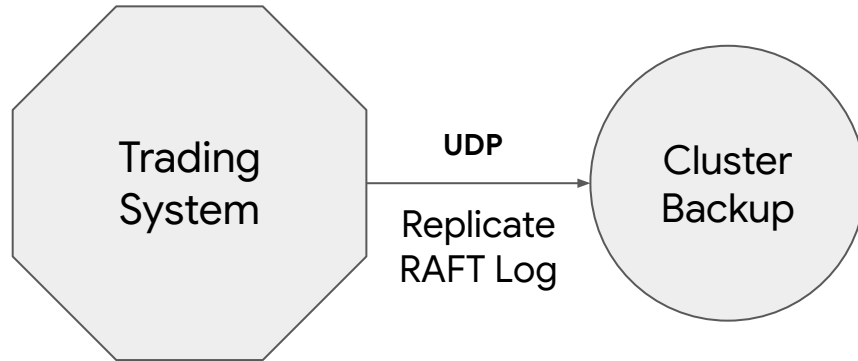

**System throughput = 1 / App processing time**

# Persisted RAFT Log

Cluster persists RAFT log (input) to disk, as per protocol

[Aeron Archive](#) API allows for replicating the RAFT log for backup

# Replicated RAFT Log

Audit - Upload to cold storage

Logging - Replay & Send to ELK outside hot path

**Debugging - Reproduce bugs locally**

**Fixing - Backfill missing events**

Testing - CI/CD replay to avoid regressions

# Replicating For Replay

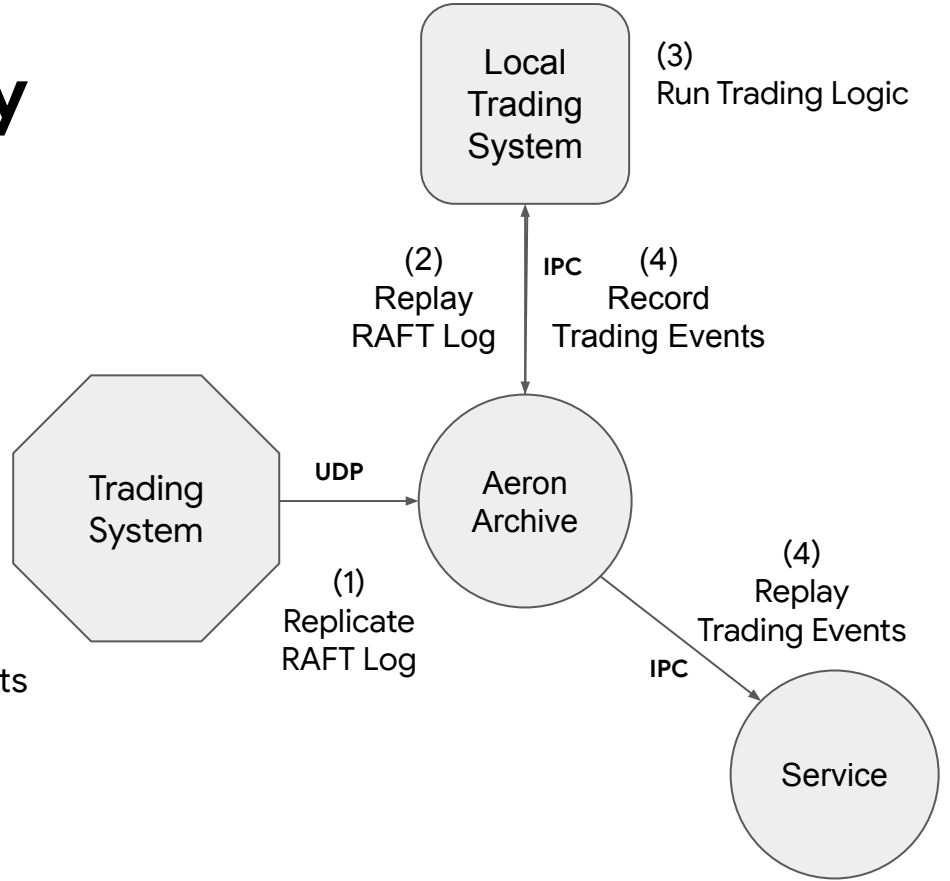

Replicate *Input*, not *Output*

Hot Path - Multicast output

Other - Replicate input & fan out

Output larger & unbounded

1 order => potentially cascading set of events

# Replicating For Scalability

Binary tree replication

Network Latency bound by  $\log(n)$

Bandwidth usage bounded

# Entire Hot Path

RTT outliers < 100  $\mu$ s

RTT medians < 50  $\mu$ s

Trading System Processing Times ~ 1  $\mu$ s

300k/s Peak Throughput

- 1) Parse & validate Order Submit
- 2) Send request to trading system
- 3) RAFT Consensus
- 4) Matching Algorithm
- 5) Send order events to gateway
- 6) Translate Order Ack

= 4 Network Hops (~20 $\mu$ s) + Processing

# Hardware Environment for CDE

Colocated in datacenter with customers

Commodity hardware

- ❖ **Intel Optane Drives**  
Faster than enterprise SSDs  
We can fsync if needed without too much penalty
- ❖ **Low Latency Switches**  
350ns cut-through forwarding  
Real-time packet capture without latency hit

Isolated NICs for low latency & bulk traffic

**Exhibit B:  
Onto the (AWS) Cloud**

# Cloud

## Cons

- Less control over hardware environment
- Need to maintain both DC/AWS deployment, toolchain, configs...

## Pros

- Codification, Collaboration
- Good enough performance
- Personal environment

# Challenge with Compute/Storage

Machine family: t, m, c, r, z , suffixes N, D

- Recommend: <https://instances.vantage.sh/>

Storage

- EBS vs Instance Storage

Orchestration

- Recommendation: Nomad

# Challenge with AWS networking

Is there a good switch on AWS?

- Cut-through:  $<0.5\mu\text{s}$
- Store & forward:  $5\mu\text{s} - 50\mu\text{s}$

# Secrets with AWS Networks

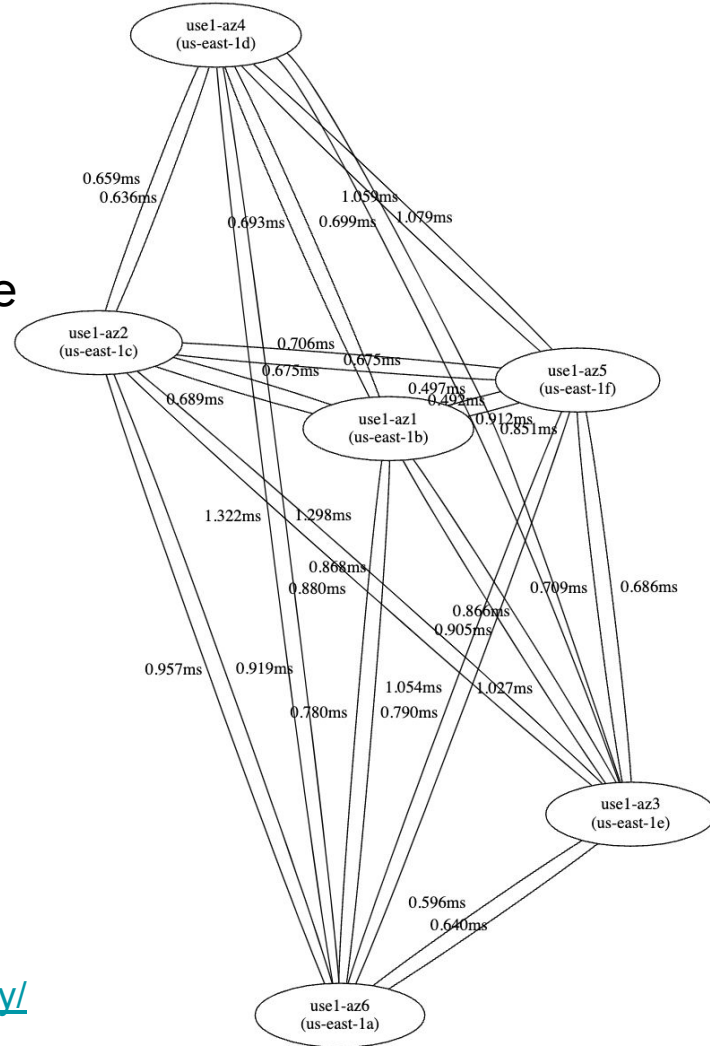

- Understand spine-leaf networking architecture
  - Region, AZ, sub-azs, racks
  - Avoid load balancers
- cluster placement group
  - capacity reservations
- bad apples

Availability Zone

📦 us-east-1a

Availability Zone ID

📦 use1-az4

<https://www.xkyle.com/Measuring-AWS-Region-and-AZ-Latency/>

# Numbers On AWS

RTT outliers < 1 ms

RTT medians < 300  $\mu$ s

Trading System Processing ~ 1  $\mu$ s

10 x Network Hops (~250 $\mu$ s)

The background features a blue-tinted scene with a brick floor in the foreground. A bright light source in the top left corner creates a lens flare and illuminates the scene. The text is overlaid on the left side of the image.

**Exhibit C:  
Deep Dive on Performance Tuning**

# Fast Memory Access

## Memory Local Data Structures

Cache locality outweighs  $O(n)$

## Primitive Friendly Data Structures

No `Map<Integer>`, avoid Boxing/Unboxing

Deserialize from memory directly into primitives

## Represent Strings as 2 Longs

128 bits => 18 7-bit (ascii) | 21 6-bit (alphanumeric) | 25 5-bit (alphabetic) | 32 4-bit (hex)

## No Allocation on Hot Path

Object Pooling

# Small Messages

## Simple Binary Encoding

### Byte Alignment Matters

FPGA Deserialization

### Order Fields By Size

### VarData / Enum / Bitsets at End

### Add Padding If Necessary

```
<types>
  <enum name="Side" encodingType="uint8">
    <validValue name="BUY">0</validValue>
    <validValue name="SELL">1</validValue>
  </enum>

  <type name="ClientOrderId" primitiveType="char" length="32">
</types>

<sbe:message name="Order" id="1">
  <field name="orderId" id="1" type="int64"/>
  <field name="price" id="2" type="int64"/>
  <field name="quantity" id="3" type="int32"/>
  <field name="side" id="4" type="Side"/>
  <field name="clientId" id="5" type="ClientOrderId"/>
</sbe:message>
```

# Java Challenges - Warmup

10k function invocations => JIT compilation  
Regulated Exchange - Cannot “warm up” our code

[Azul Zulu Prime JVM - ReadyNow!](#)

Cache and Persist JIT Profile + Optimizations  
Pre-train new releases with multiple replays of PROD logs

Fast initial orders, remove JIT compilation jitter

# Java Challenges - Garbage Collection

“Stop The World” GC - All Application Threads Stalled

Java 8 - [Concurrent Mark Sweep](#)

Azul Zulu Prime JVM - Pauseless Garbage Collector

[Azul C4 Garbage Collector](#)

# Network Optimizations

## Multicast

- Consensus

- Output to order and market data gateways

## Aeron - High Performance Messaging

- Reliable Transport over UDP

- Per-channel settings

  - Congestion & Flow Control

  - Socket Buffers - # data in flight ideally equal to Bandwidth Delay Product

  - MTU - Jumbo Frames (9k) for batching

# Network Optimizations

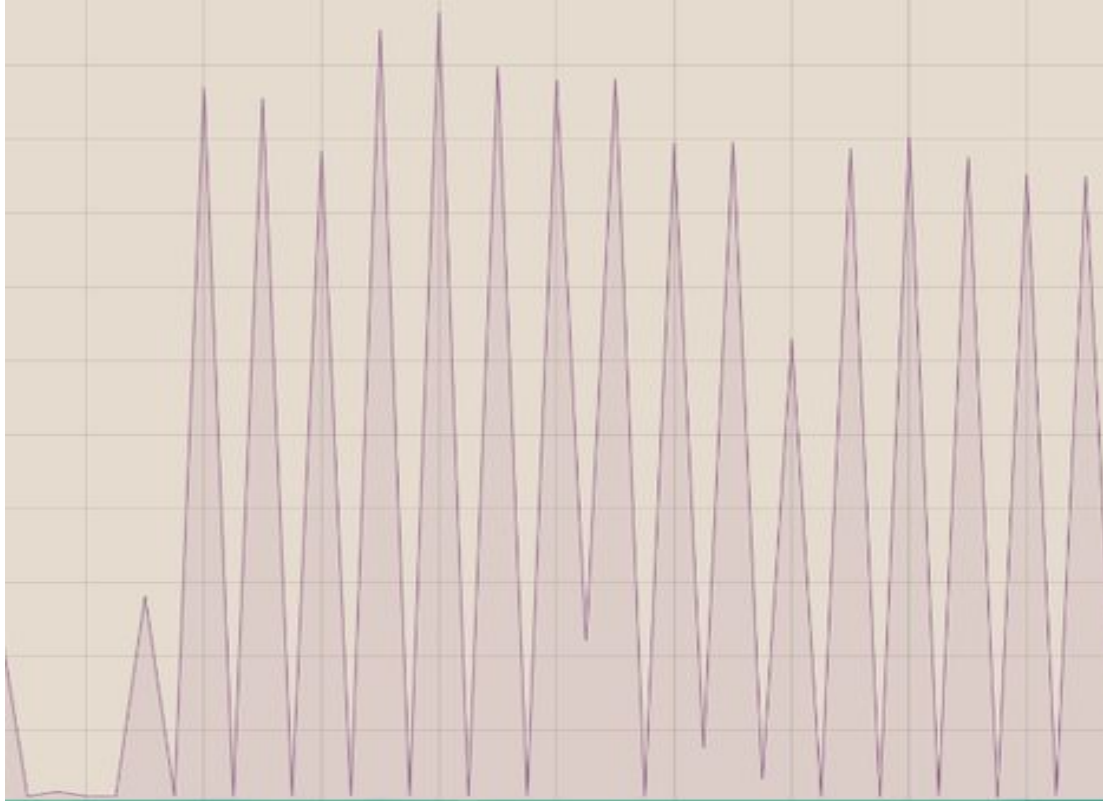

## Kernel Bypass

Read from network card directly from user space  
Decreases median, drastically reduces outliers  
OpenOnload in data center w/ SolarFlare NICs  
DPDK in the cloud - [Aeron Support](#) (premium)

Aeron point-to-point  
Sending as fast as possible on AWS

	Mean	Max	Throughput
non-DPDK	38 $\mu$ s	<b>1897<math>\mu</math>s</b>	80MB/s
DPDK	28us	<b>515<math>\mu</math>s</b>	500MB/s

# Medians Good, Outliers Spiky

Weeks Before Launch

# OS Scheduling Delay / Context Switches

How are CPU cycles are not running your hot threads?

## /proc/sched\_debug - task running time per CPU

# OS Scheduling

Pin hot threads to hardcoded CPUs (taskset, sched\_setaffinity)

Prevents context switching & cache misses

Isolate hot CPUs or prioritize threads (ISOLCPUS, taskset, cpuset, nice, chrt)

Prevent other user threads from taking CPU time

Busy-spin hot threads to monopolize CPU (and for polling)

Set affinities to hardware interrupts, kernel workqueues, etc.

Hardware interrupts - use tuna, or set /proc/irq/<irq#>/smp\_affinity

Softirq kernel params - rcu\_nocbs, nohz\_full

# Other Tuning

## NUMA locality

If you have multiple CPU sockets, one is closer to NIC and memory  
Layout matters - lock hot threads to that CPU / Memory NUMA node

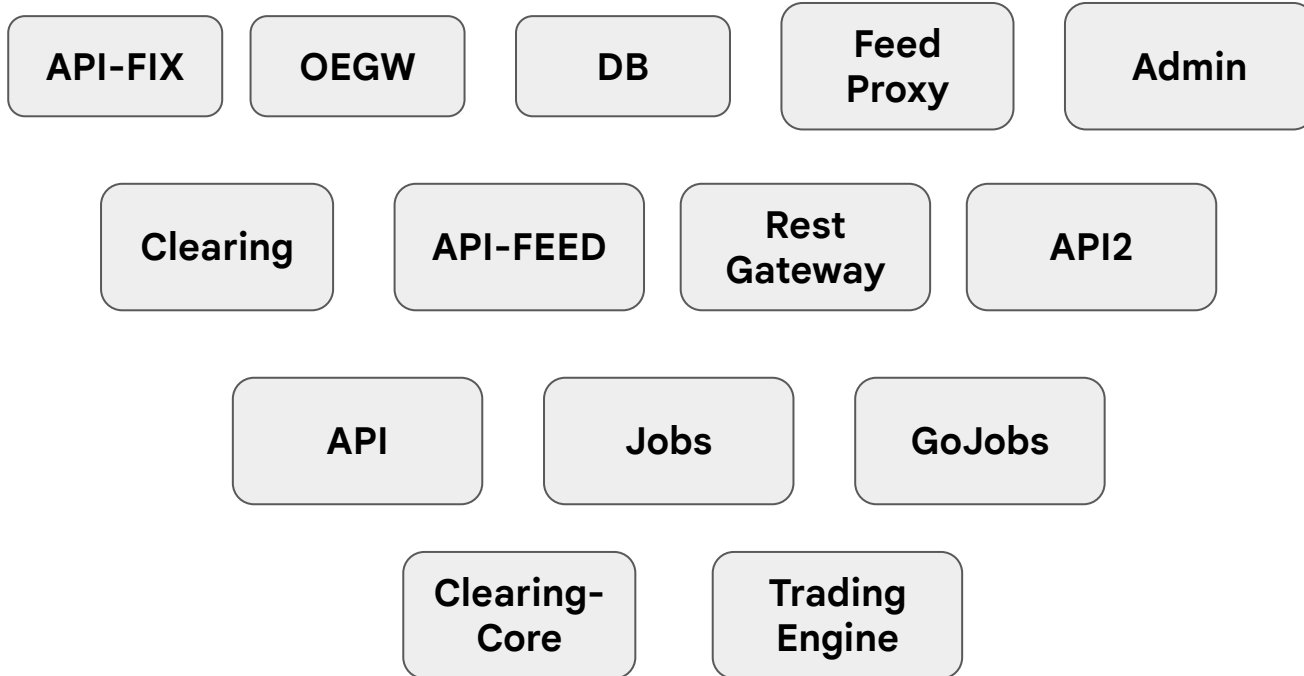

## Hyperthreading

Turn it off (or isolate corresponding logical CPU)  
More available L1/L2 cache without it

**Exhibit D:**  
**Apply the learnings to improve**  
**The Legacy System**  
**Where the real fun begins...**

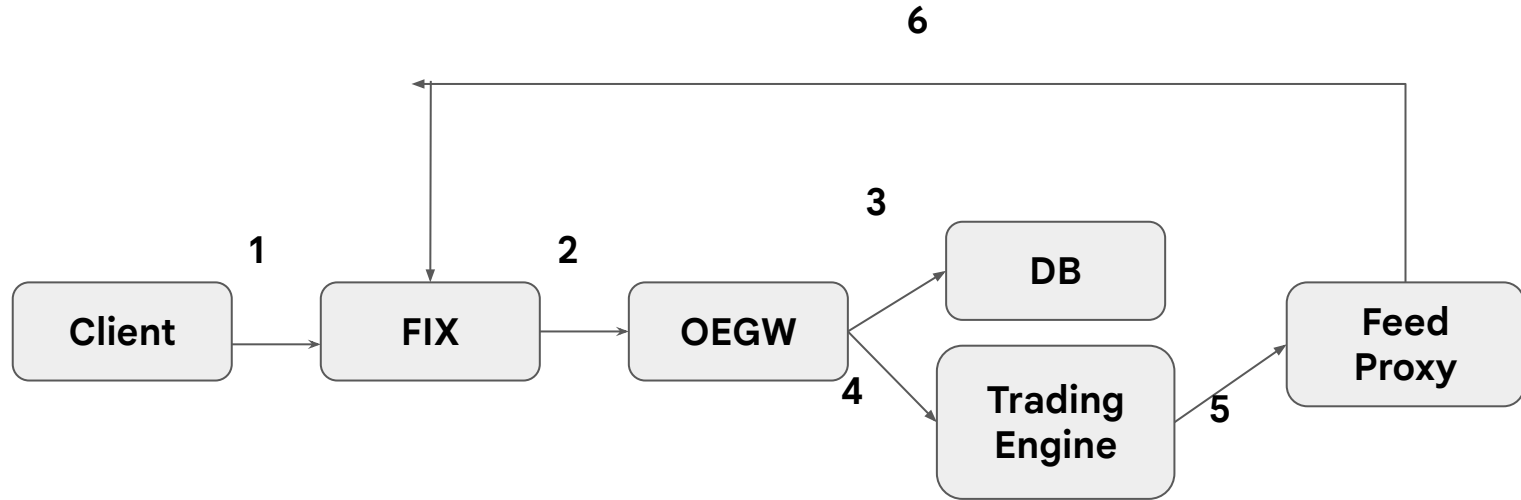

# Fun with MicroServices

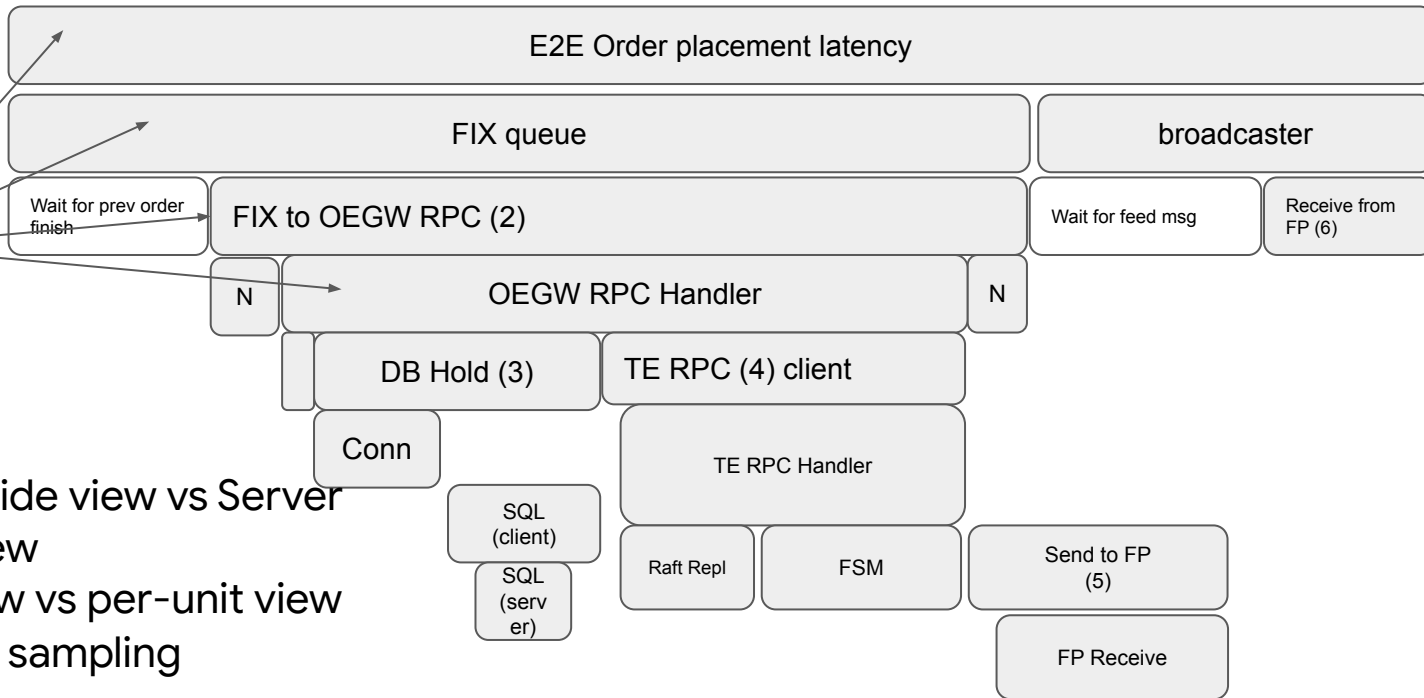

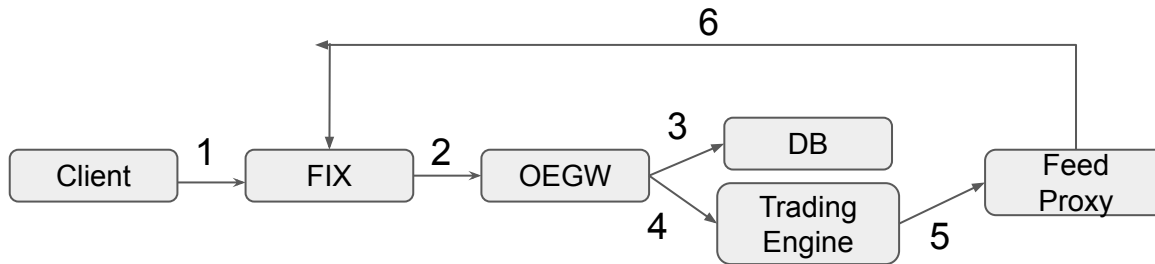

Solution: Another dashboard???

# Life of an request

Tracing an single order placement request from start to finish

Graph Everything !!!

**Beware:**

- Client side view vs Server Side view
- E2E view vs per-unit view
- Tracing sampling

# Happy Path: min/p50

~1200us: Elevated but not that outrageous

**Infra Inefficiencies** - 1000us -> 600us  
vs 50us

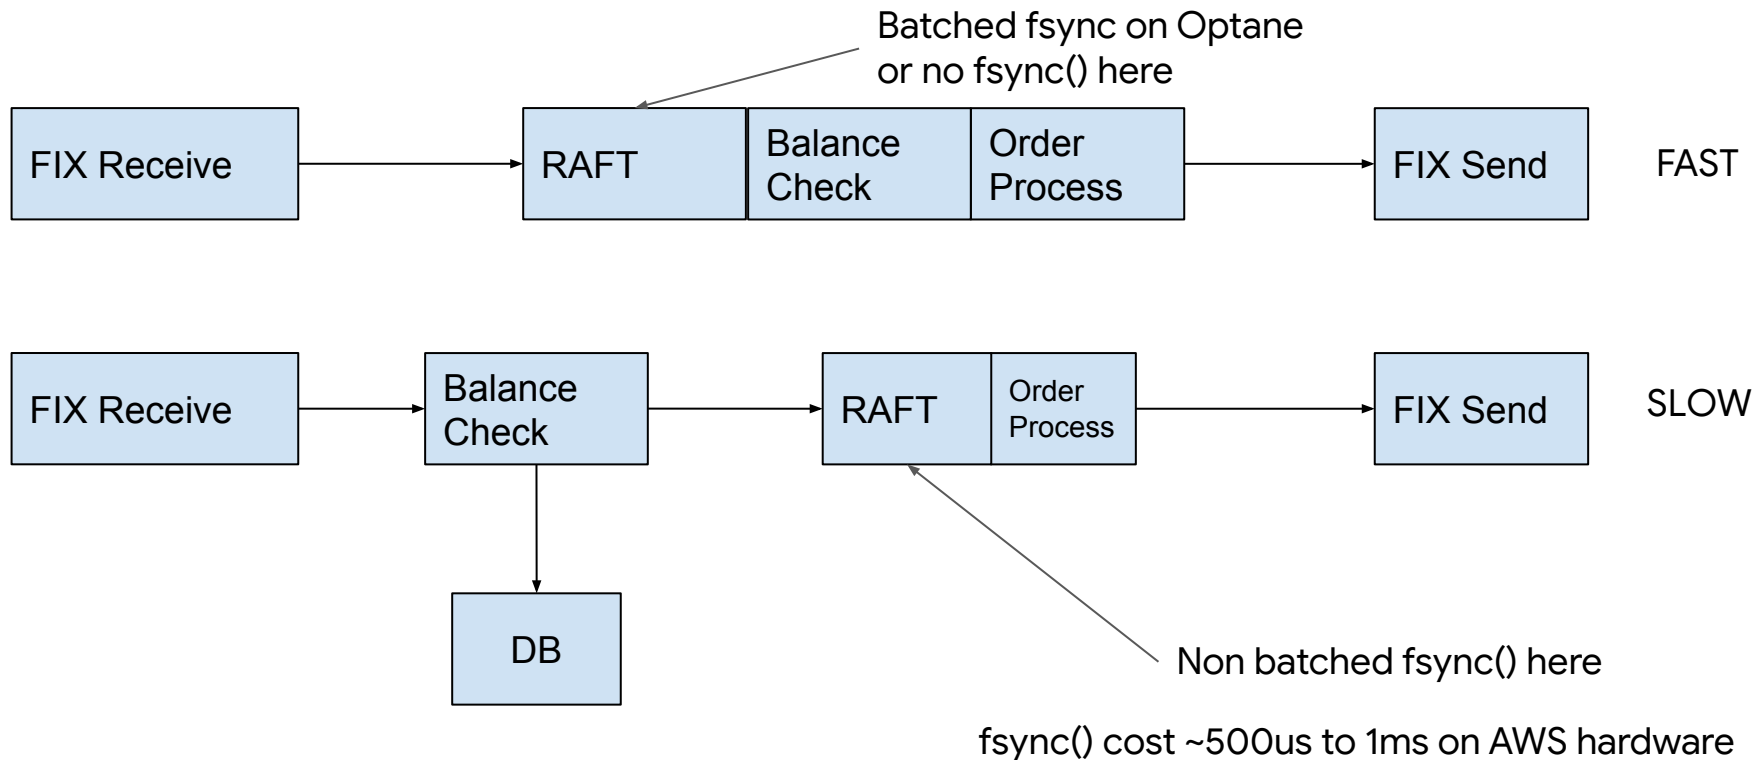

- Compute/Storage
- Network latency
  - Cross AZ traffic
  - Load balancer
- fsync()s

**Per operation cost** - 30us vs 1us

- Full native, no warmup issue
- Allocations, Pointers
- Metrics recording / Logging

Do you know how often your datadog metrics call is sending a UDP packet out?

# Is it just misplaced fsync()s?

# Pointer & Memory Allocations In Golang

Heap escape analysis (-gcflags “-m”)

- Sending pointers or values containing pointers to channels.
- Storing pointers or values containing pointers in a slice. like `[]*string`.
- Backing arrays of slices that get reallocated because an `append` would exceed their capacity.
- Calling methods on an interface type

Pass a small struct by value could be 8x faster vs passing by pointer, thus moving it to the heap. (x86\_64 has cache line size 64 bytes)

<https://segment.com/blog/allocation-efficiency-in-high-performance-go-services/>

# Unhappy Path: p99/max

P99 ~4ms, Max 362ms

WTF is going on...

- GC pause?
- Scheduling delays?
- Non-FIFO behaviors?

# Is Golang GC really a issue?

## SLOs then and now

1.

### 2014

25% of the total CPU

Heap 2X live heap

10 ms STW pause every 50 ms

Goroutines allocation  $\propto$  GC assists

### 2018

25% of the CPU *during* GC cycle

Heap 2X live heap or max heap

Two <500  $\mu$ s STW pauses per GC

Goroutines allocation  $\propto$  GC assists

Minimal GC assists in steady state

~~10~~ms  $\rightarrow$  1ms  
Old Max Pause Time      New Max Pause Time

<https://tip.golang.org/doc/gc-guide>

# Hint: Goroutine explosion by GRPC

Golang grpc unary requests default to create new goroutine for every request, this cause starvation of any background goroutines, leads to tail latencies

Goroutines:

[runtime.gcBgMarkWorker](#) N=95

[google.golang.org/grpc.\(\\*Server\).serveStreams.func1.2](#) N=34041

[github.com/hashicorp/raft.\(\\*raftState\).goFunc.func1](#) N=14

[google.golang.org/grpc/internal/transport.NewServerTransport.func2](#) N=17

[google.golang.org/grpc.\(\\*Server\).handleRawConn.func1](#) N=17

[github.com/cbhq.net/engineering/csf/go/csf.\(\\*DefaultSystemManager\).AddService.func1](#) N=6

[github.com/hashicorp/raft.newNetPipeline.dwrap.40](#) N=4

[github.com/cbhq.net/mono/repo/pro/trading-engine/engine/internal/replicator.\(\\*Replicator\).Run.func1](#) N=1

[runtime.bgsween](#) N=1

# Hint: Goroutine scheduler delay

Goroutine Name: `github.cbhq.net/mono/repo/pro/trading-engine/engine/internal/replicator.(*Replicator).Run.func1`

Number of Goroutines: 1

Execution Time: 1.52% of total program execution time

Network Wait Time: [graph\(download\)](#)

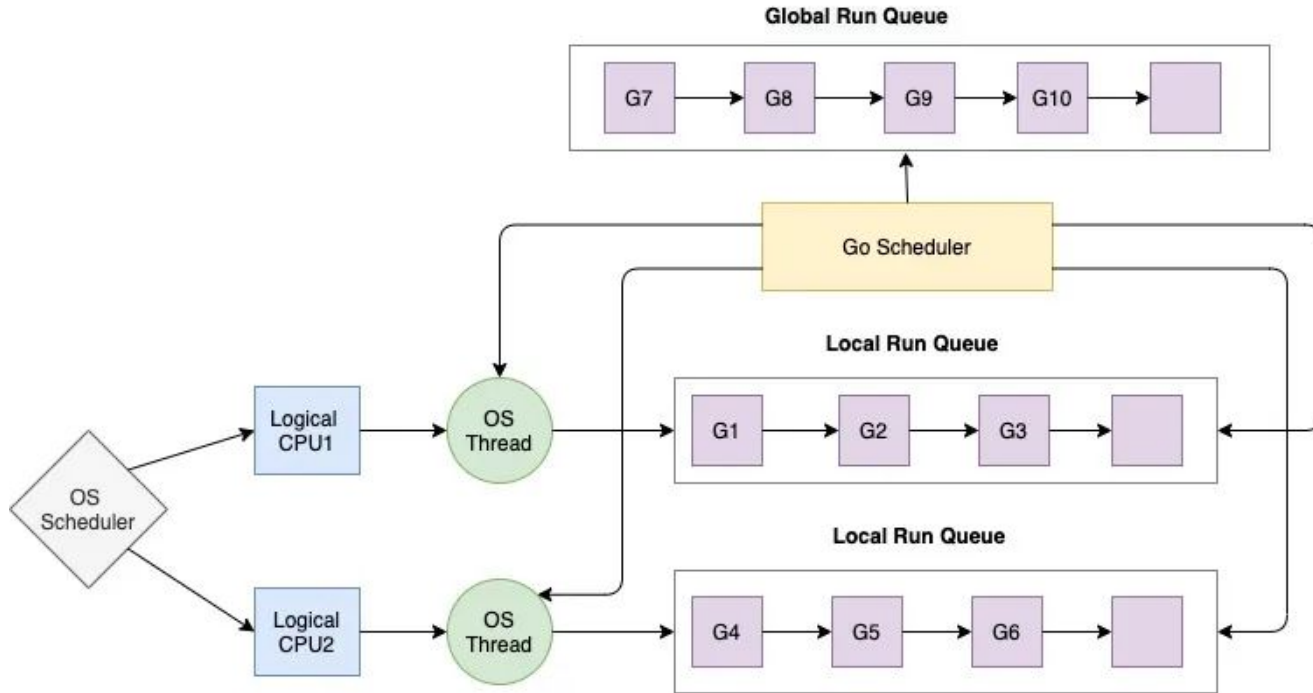

Sync Block Time: [graph\(download\)](#)

Blocking Syscall Time: [graph\(download\)](#)

Scheduler Wait Time: [graph\(download\)](#)

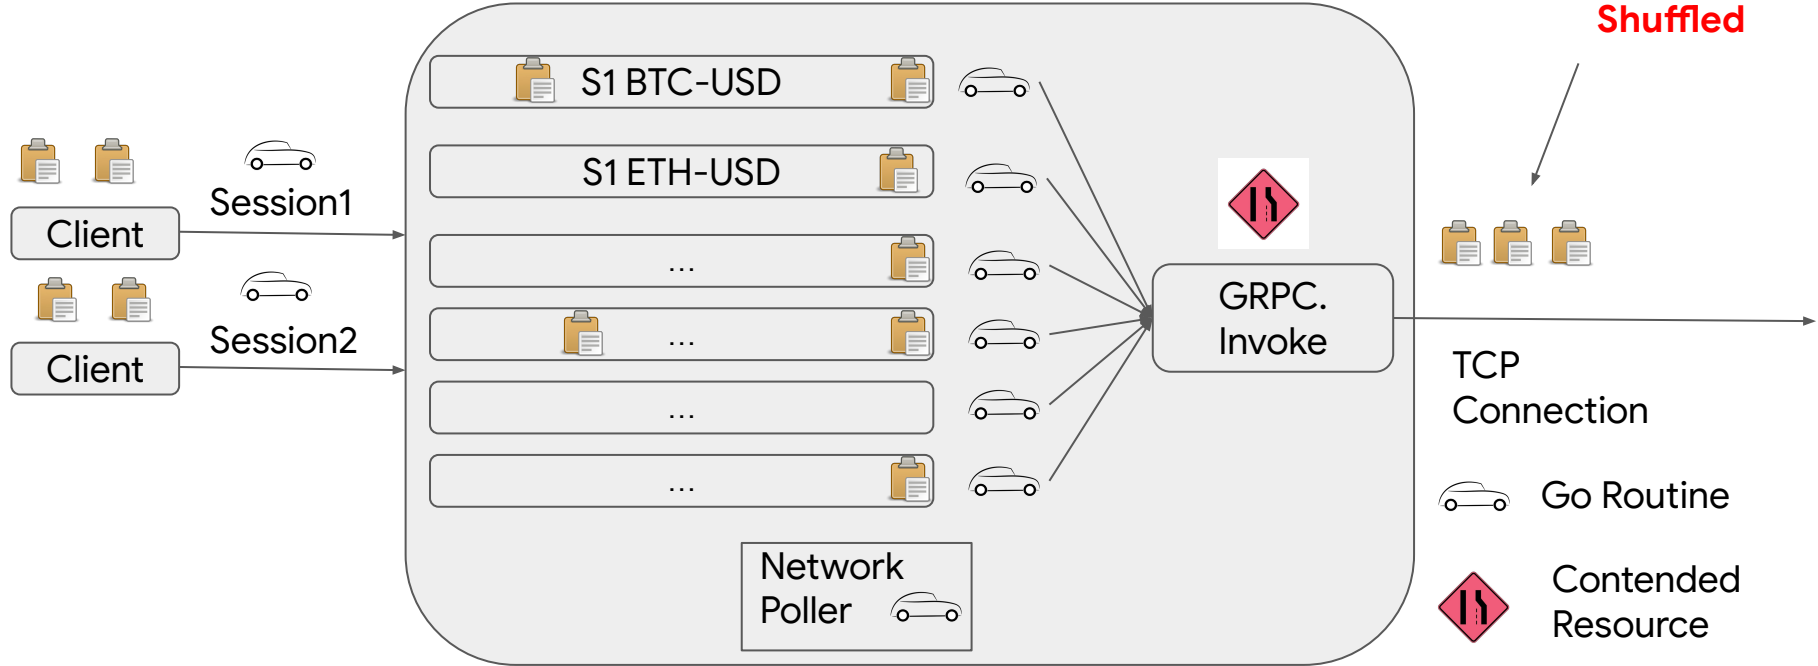

Goroutine Total		Execution	Network wait	Sync block	Blocking syscall	Scheduler wait	GC sweeping	GC pause
<a href="#">181</a>	10s	956ms	0ns	8670ms	0ns	373ms	3416 $\mu$ s (0.0%)	230ms (2.3%)

# Goroutine is not your good old thread

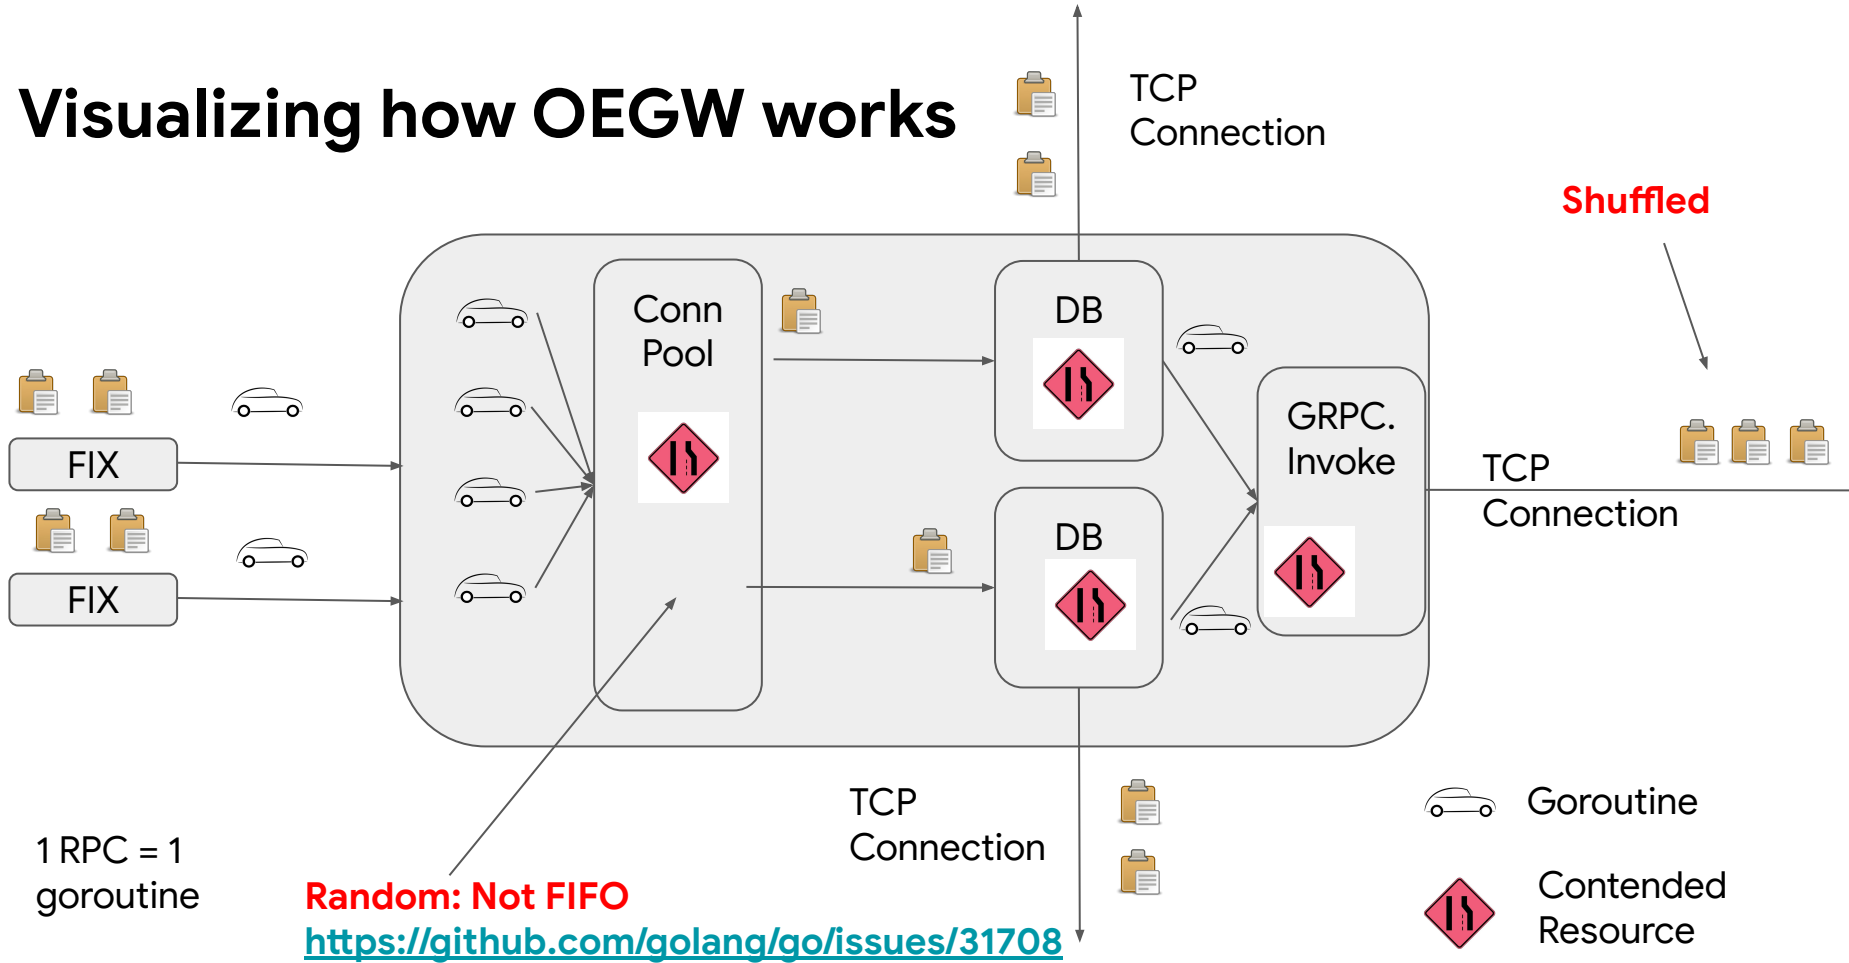

- [Go scheduler](#)
- GOMAXPROCS = num CPUs
- Remember: Only GOMAXPROCS will run at same time

# Visualizing how API-FIX works

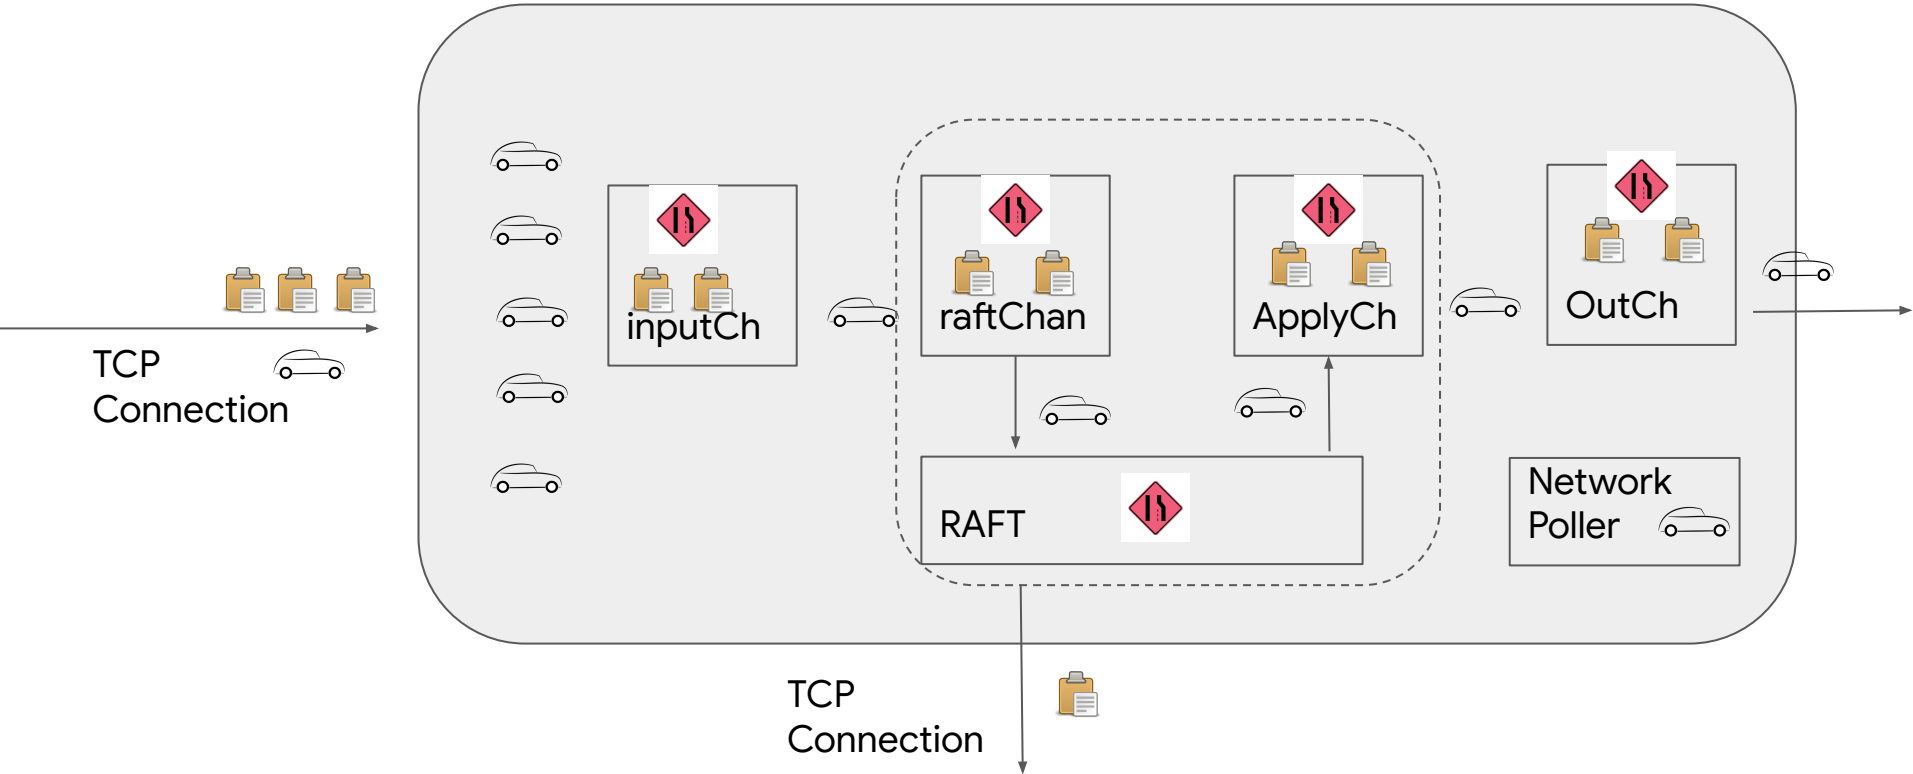

**REMEMBER: Only GOMAXPROCS amount of goroutines will run at any given time**

# Visualizing how OEGW works

# Visualizing how Trading Engine works

**REMEMBER: Only GOMAXPROCS amount of goroutines will run at any given time**

# Mitigations: spinning important goroutine

```
select {
    case item <- ch:
        // process item
}
```

```
select {
    case item <- ch:
        // process item
    default:
        // busy spinning
        continue
}
```

Note: Golang scheduler will force preempt long running go-routines every 10ms

## Challenges:

Can't spin too much, as you will run out of CPU and cause starvation.

**runtime.LockOSThread()**

# Mitigations: Always batch when using channels

```
select {  
case item <- bufCh:  
    items := make([]int, 20)  
    items = append(items, item)
```

First Read

Remaining:

```
for i := 0; i < 19; i++ {  
    select {  
    case item <- bufCh:  
        items = append(items, item)  
    default:  
        break Remaining  
    }  
}
```

Grab outstanding  
messages while you  
are there

Why does this work?

- Avoid scheduler delays
- Better cache locality

```
    // processing items  
default: continue  
}
```

Don't forget spinning!

# Realization: Golang is optimized for throughput

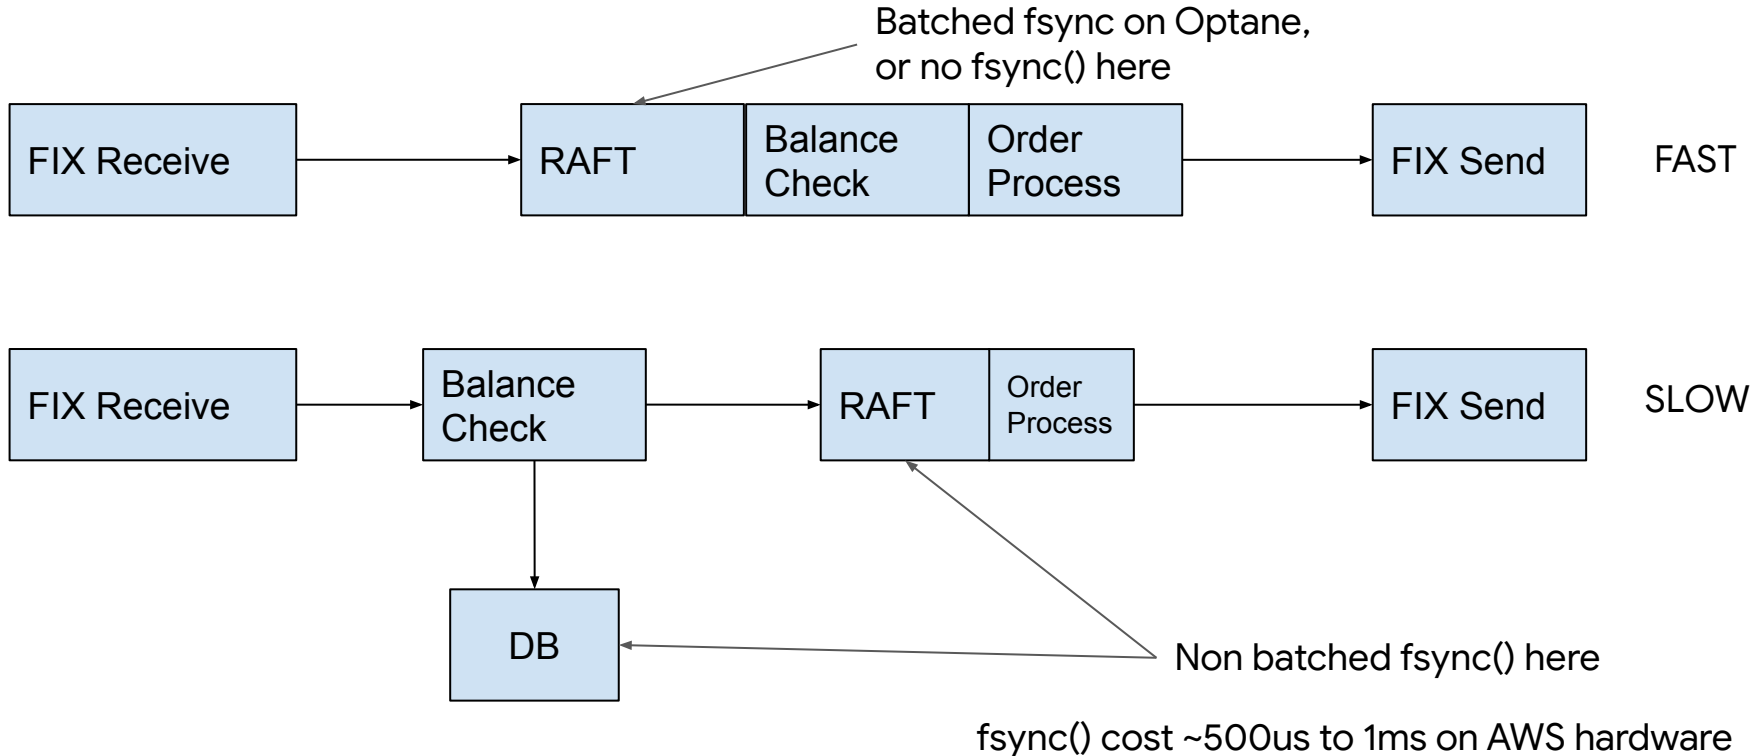

Most facilities in ~~Golang~~ Linux introduce an randomness element to optimize for throughput, not latency

- Go encourage you/libraries to spawn adhoc goroutines everywhere
- No goroutine priorities, and scheduler is randomized and job stealing

Writing low latency code in Golang is not easy, but again it's not easy anywhere else either.

Recommendation: use GRPC in streaming mode, not unary mode!

# Is it just misplaced fsync()s?

...“let’s add this part or the process step in case we need it”... the most common error of a smart engineer, is to optimize the thing that should not exist....

Elon Musk on Engineering, interviewed by Tim Dodd

## Latency Cost Rankings

- <1us Kernel syscall overhead
- ~ 1us optimized application logic cost
- ~ 5us kernel context switching cost
- ~ 5us per network hop on LT hardware
- ~ 25us per network hop on AWS hardware
- ~ 30us per message unoptimized application logic cost
- ~ 50us - 100us RT Kernel scheduler delay [0]
- ~ <100us fsync on Optane
- ~ 250us golang GC pauses
- ~ 1ms fsync on AWS Instance Storage
- ~ N ms non-RT Kernel scheduler delay [0]
- ~N to NNms golang scheduler delays
