**Query: return all frames last week that contains a bus**

# Trends of surveillance cameras

- Low-cost, wireless cameras grow exponentially and enable ubiquitous intelligence
- Most videos are *cold* (i.e., never used till deletion)
  - We target retrospective query

A campus spanning around 1mi<sup>2</sup>

- equipped more than 1,000 cameras

Analysis over 6-month 3,000,000 hours of videos (around 5.4PB) show that:

- Only **<2%** cameras were used
- Only **<0.005%** video data was used

# Trends of surveillance cameras

- Low-cost, wireless cameras grow exponentially and enable ubiquitous intelligence
- Most videos are *cold* (e.g., never used till deletion)
- Transmitting cold videos wastes precious wireless bandwidth

$$\text{Network Usage} = \text{Bitrate} * \text{Cameras} * \text{Time}$$

(Wireless) bandwidth is for user applications (e.g., video streaming), not cold videos!!

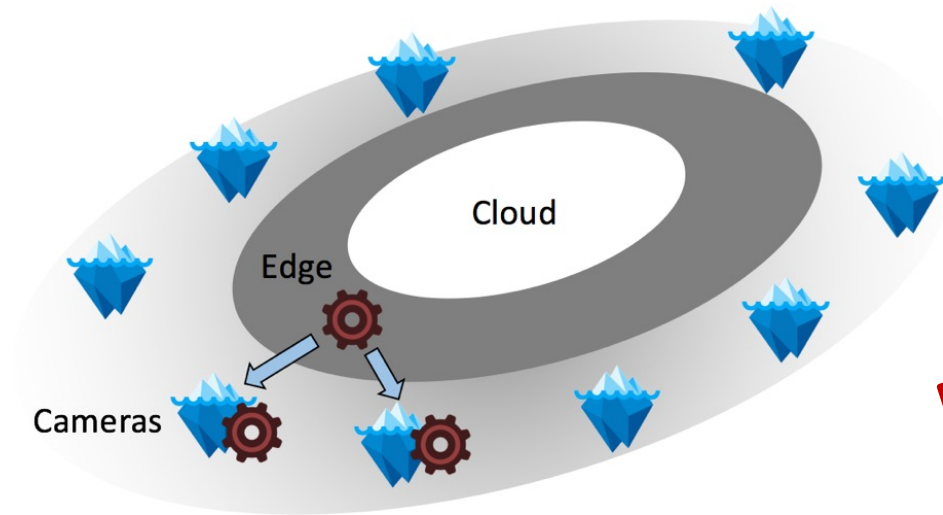

# Trends of surveillance cameras

- Low-cost, wireless cameras grow exponentially and enable ubiquitous intelligence
- Most videos are *cold* (e.g., never used till deletion)
- Transmitting cold videos wastes precious wireless bandwidth
- Cheap camera storage can retain videos long enough (weeks to months)

# Zero-streaming (ZS) cameras

1. Cameras store videos locally during capture time
2. Cameras respond to servers during query time

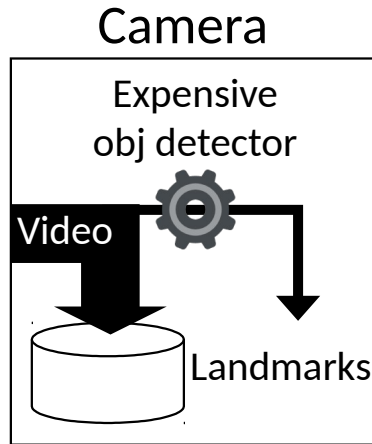

**Network/compute resource provisioned  
on-demand – good for resource efficiency**

# Zero-streaming (ZS) cameras

1. Cameras store videos locally during ingestion time
2. Cameras respond to servers during query time

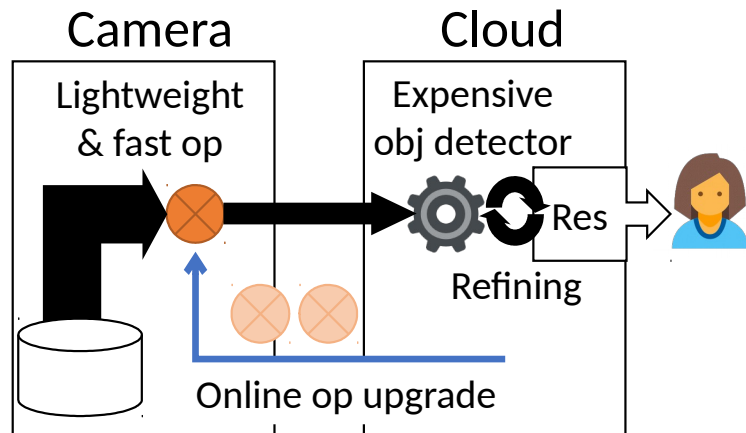

- A key question: how can we query **fast**?
- Challenges we are facing:
  - Cameras are wimpy (No GPU, RaspberryPi-like)
  - Network limited (the bottleneck!)
  - User are waiting (return something useful AFAP)
  - ...

# DIVA: a runtime for ZS cameras

**Capture time:** building **landmarks** to capture reliable video knowledge

- e.g., in which video areas buses usually appear

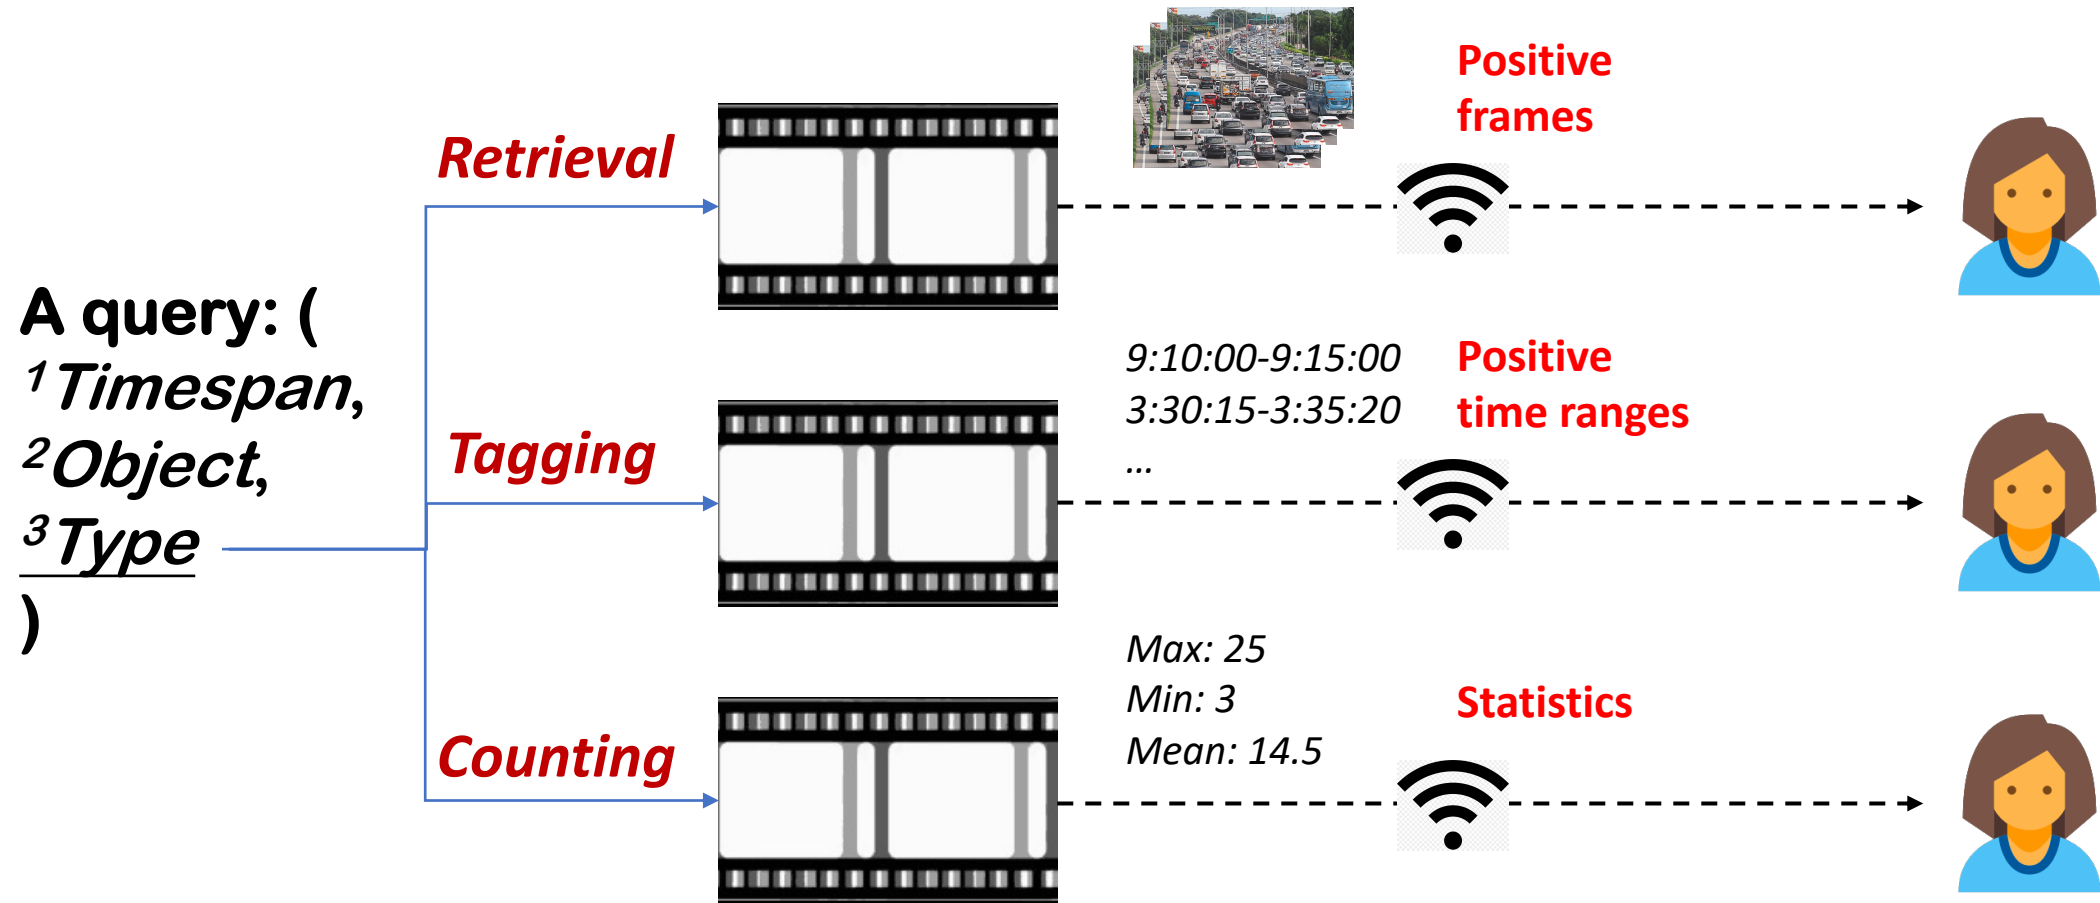

**Query time:** run NNs on camera to prioritize/filter frames to be sent, and update the NNs

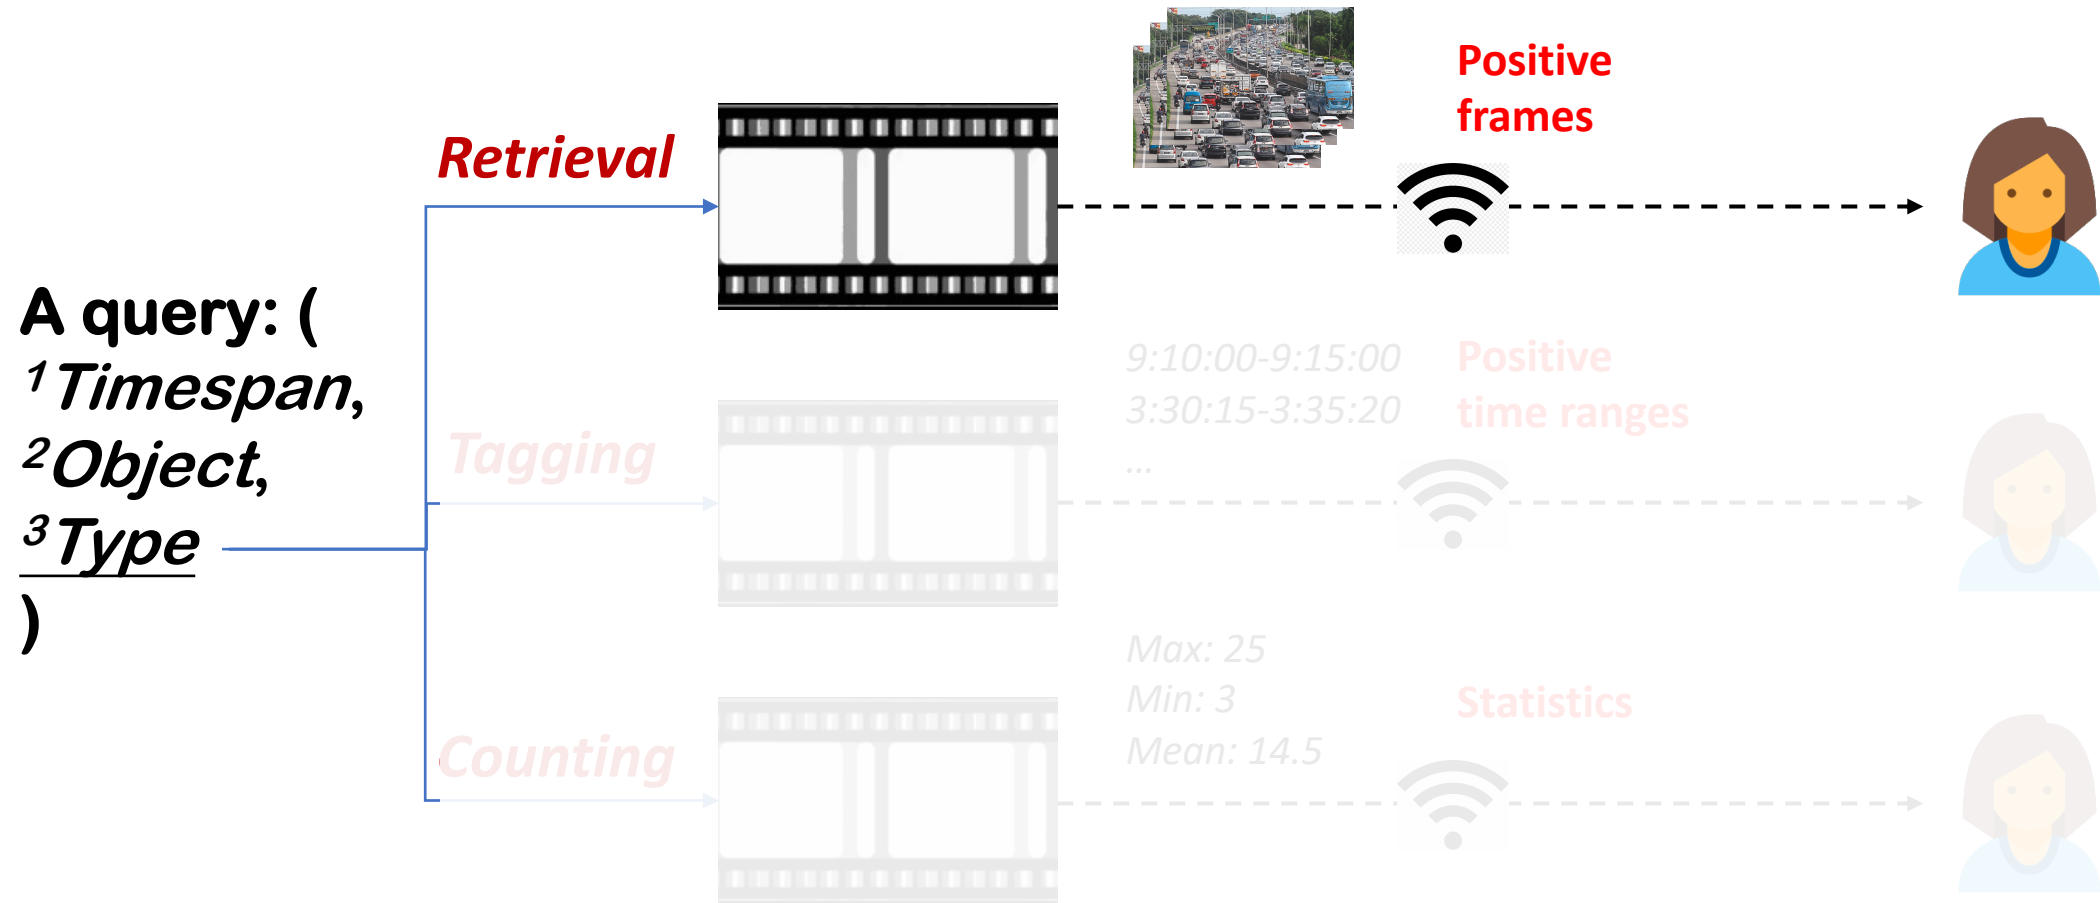

- Results to users are continuously refined

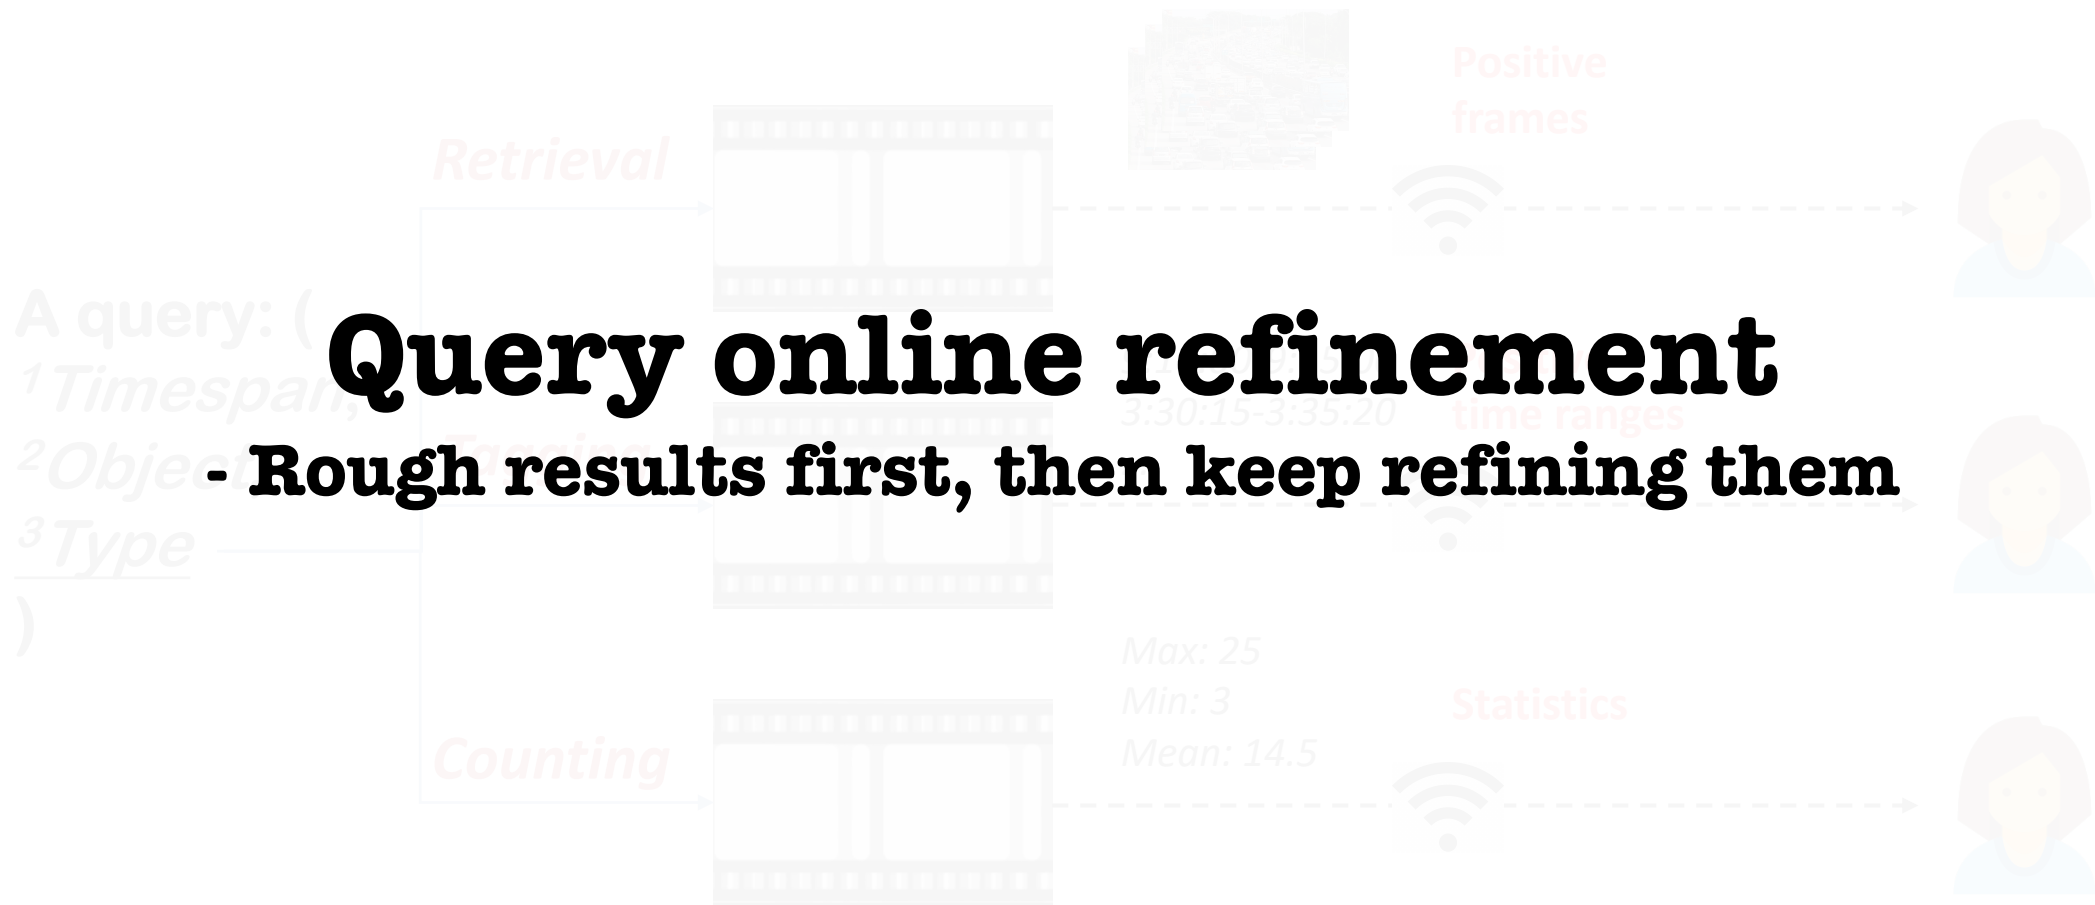

# Supported query types in DIVA

# Supported query types in DIVA

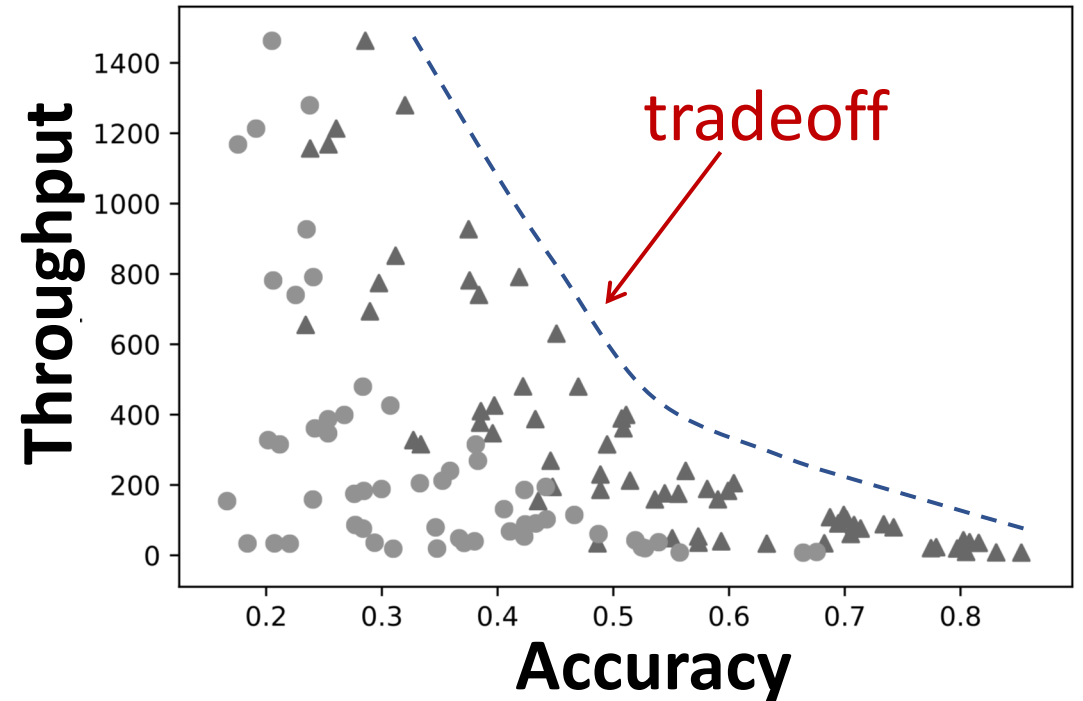

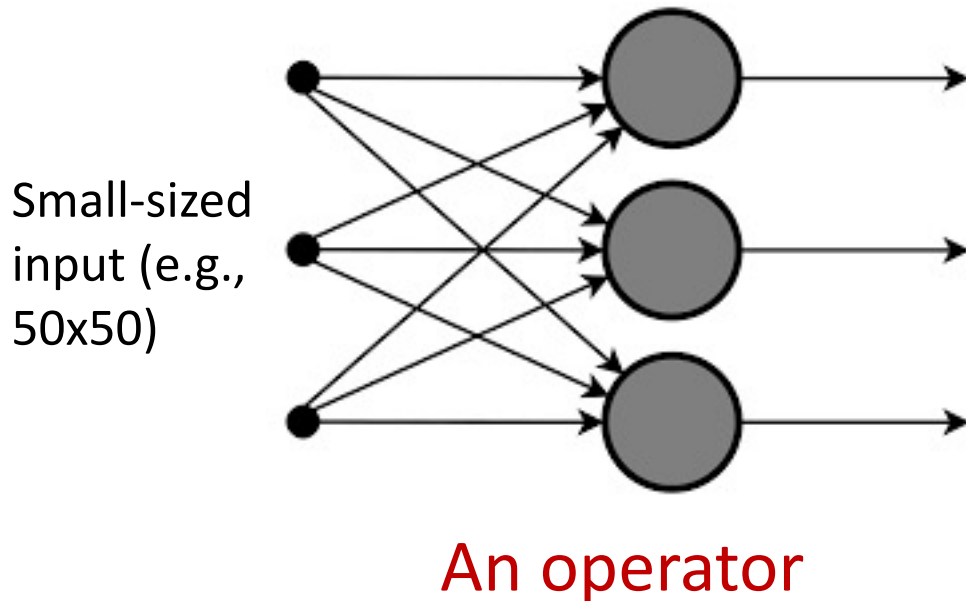

# Supported query types in DIVA

# Basics: operators

- Nothing but small neural networks (NNs)
  - Small enough to run fast on cameras (x100s FPS)
  - Rich *accuracy-throughput* tradeoff

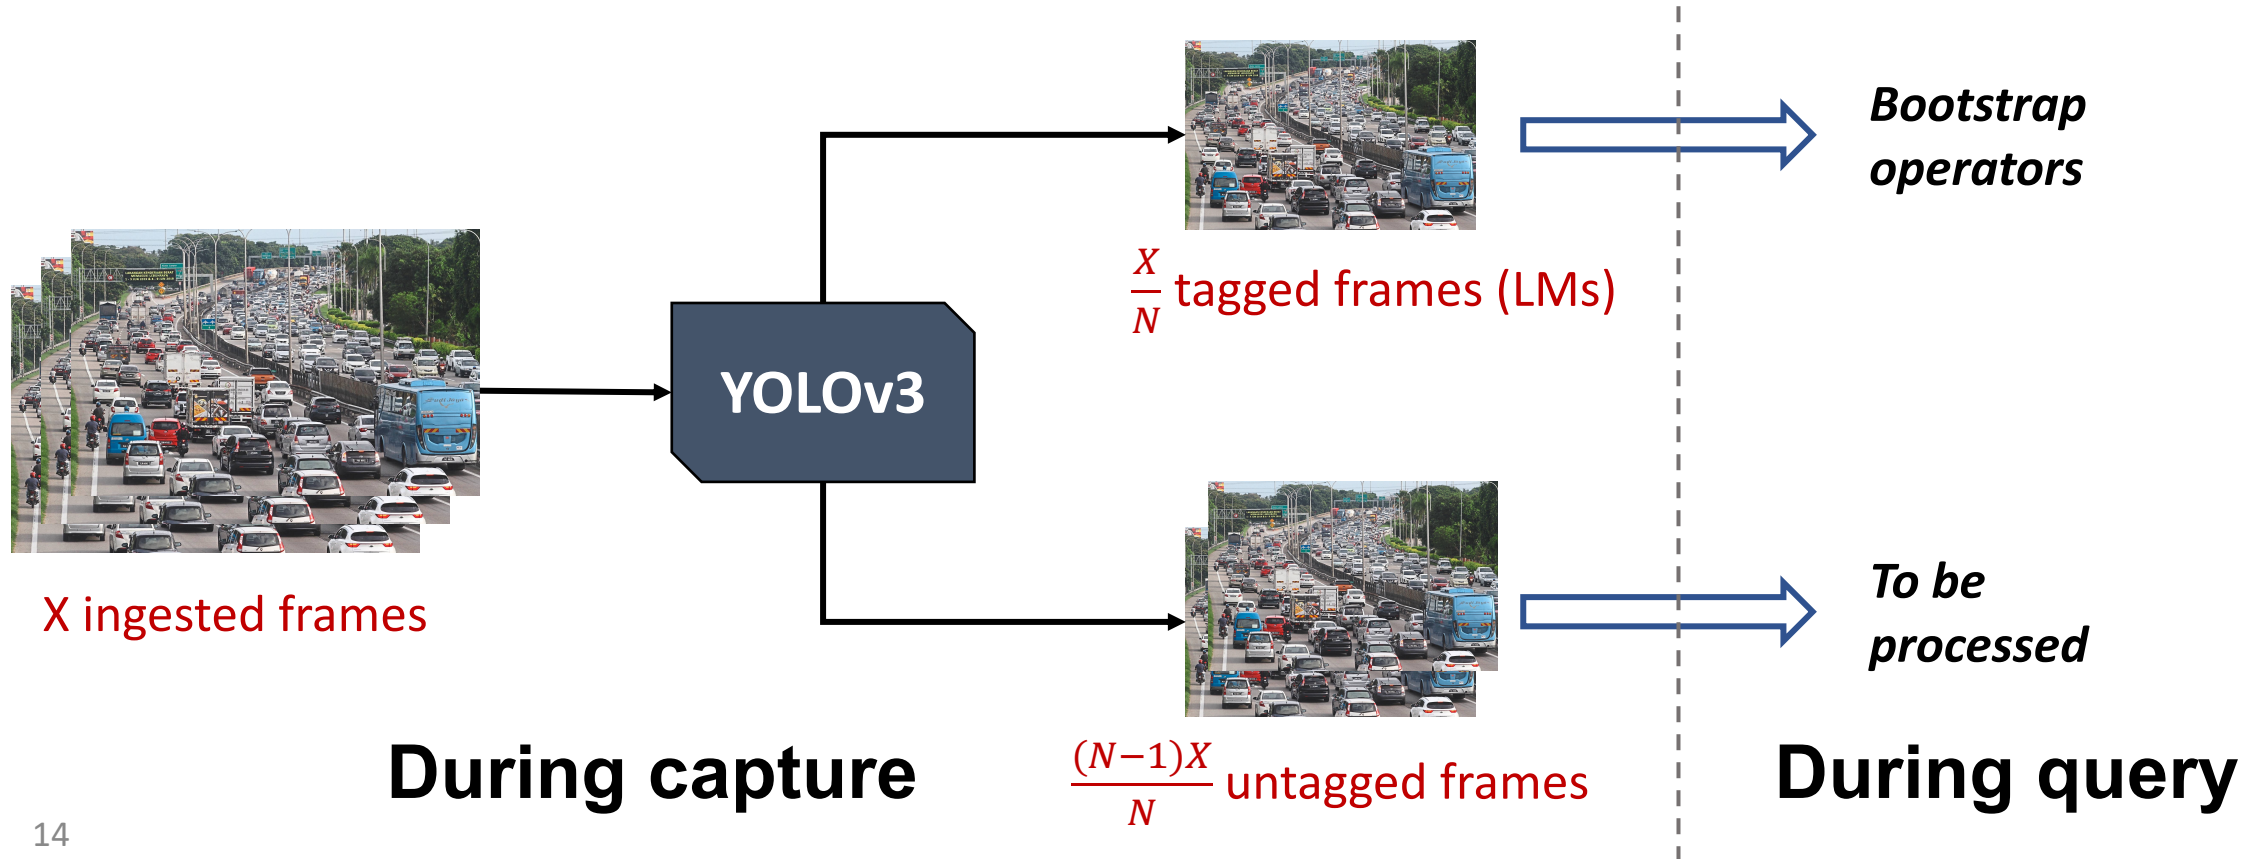

# Basics: operators

- Nothing but small neural networks (NNs)
  - Small enough to run fast on cameras (x100s FPS)
  - Rich *accuracy-throughput* tradeoff
- How operators serve? As *rankers* or *filters*

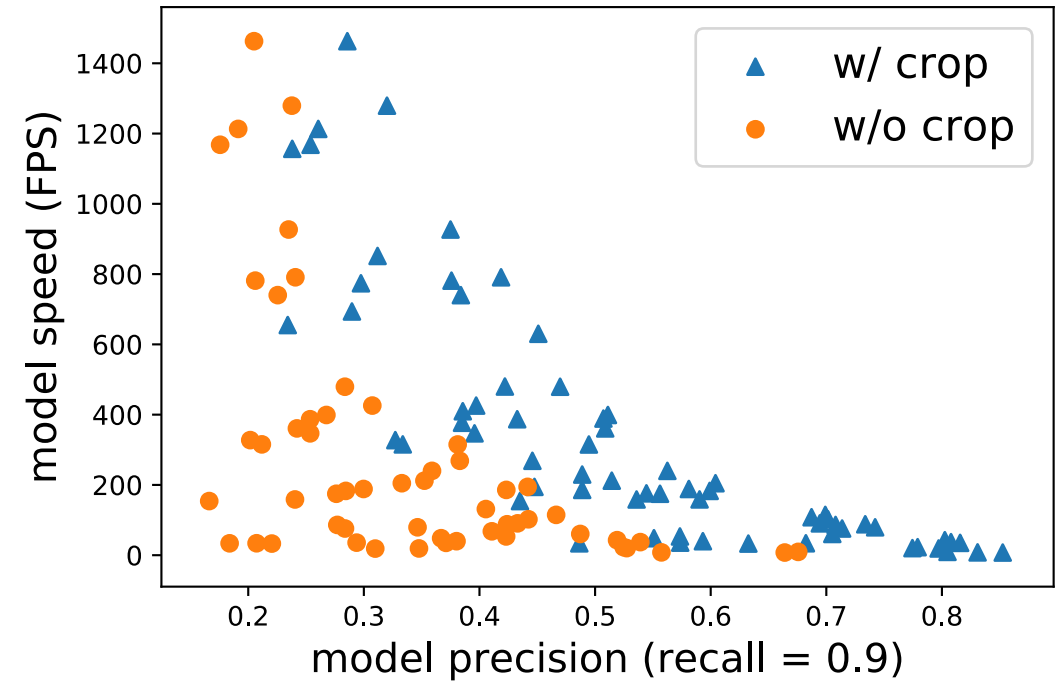

# Design #1: landmarks (capture time)

- Running the expensive model on captured frames regularly (sparsely)
- Landmarks are used to train operators

# Design #1: landmarks (capture time)

- Key idea: exploiting spatial skews of video objects
  - So operators can be more focused on areas of interests

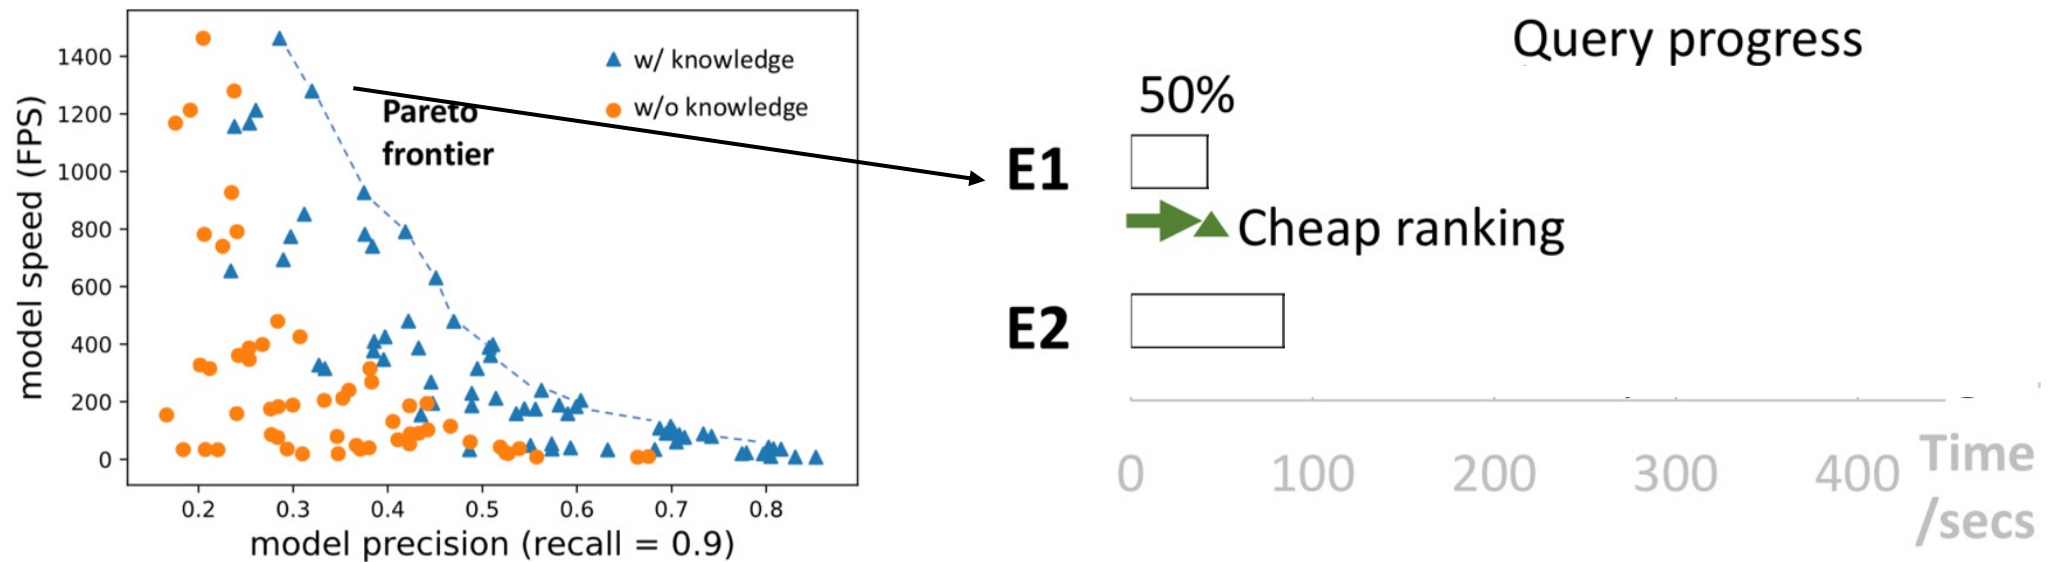

**Object spatial skews is pervasive**

**Cropping improves op performance**

# Design #2: operator upgrade (query time)

- What operator to use? No silver bullet!

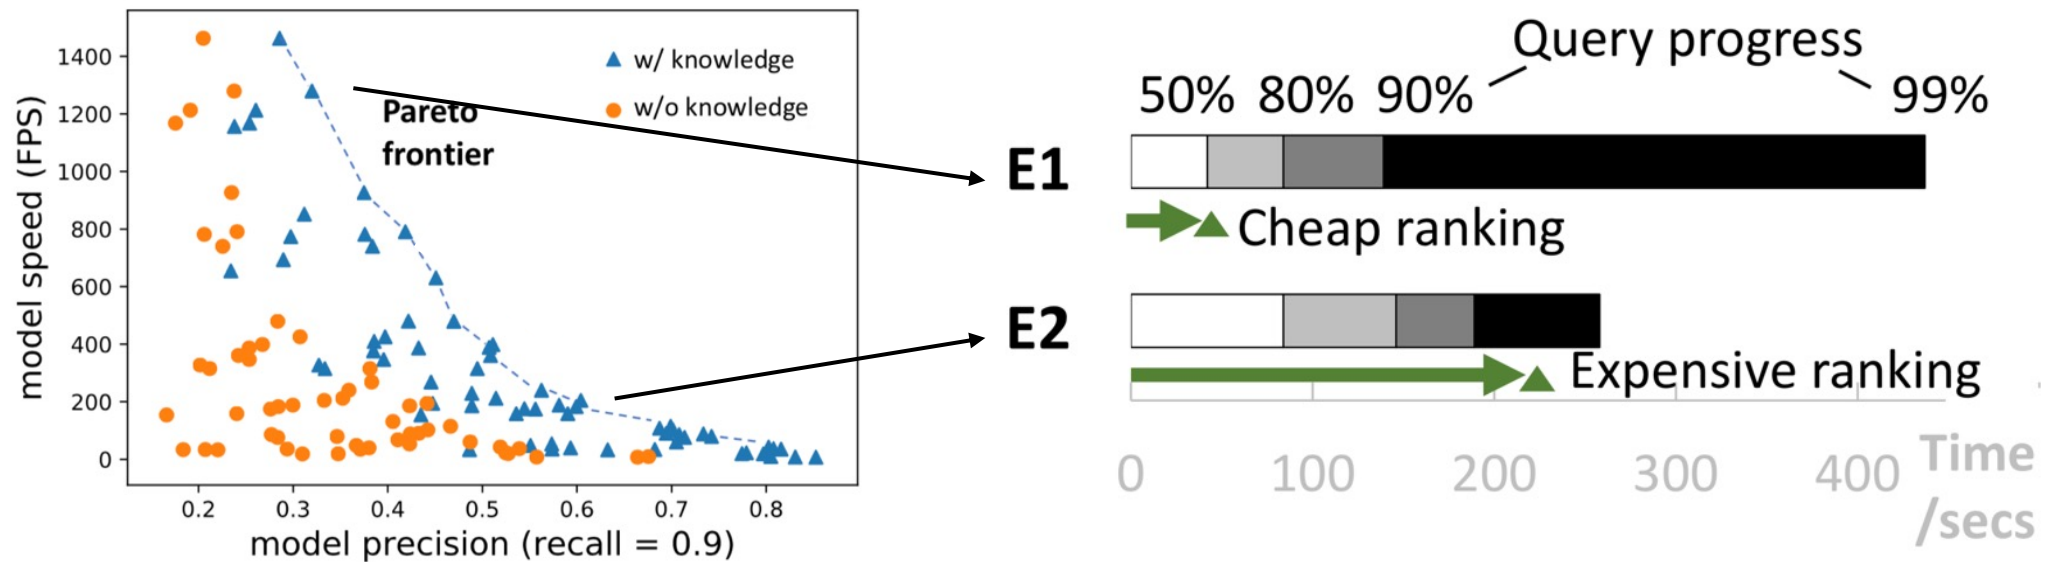

**Fast (yet inaccurate) operators win at early stage**

# Design #2: operator upgrade (query time)

- What operator to use? No **silver bullet**!

**Accurate (yet slow) operators win at later stage**

# Design #2: operator upgrade (query time)

- Multipass, multi-operator execution

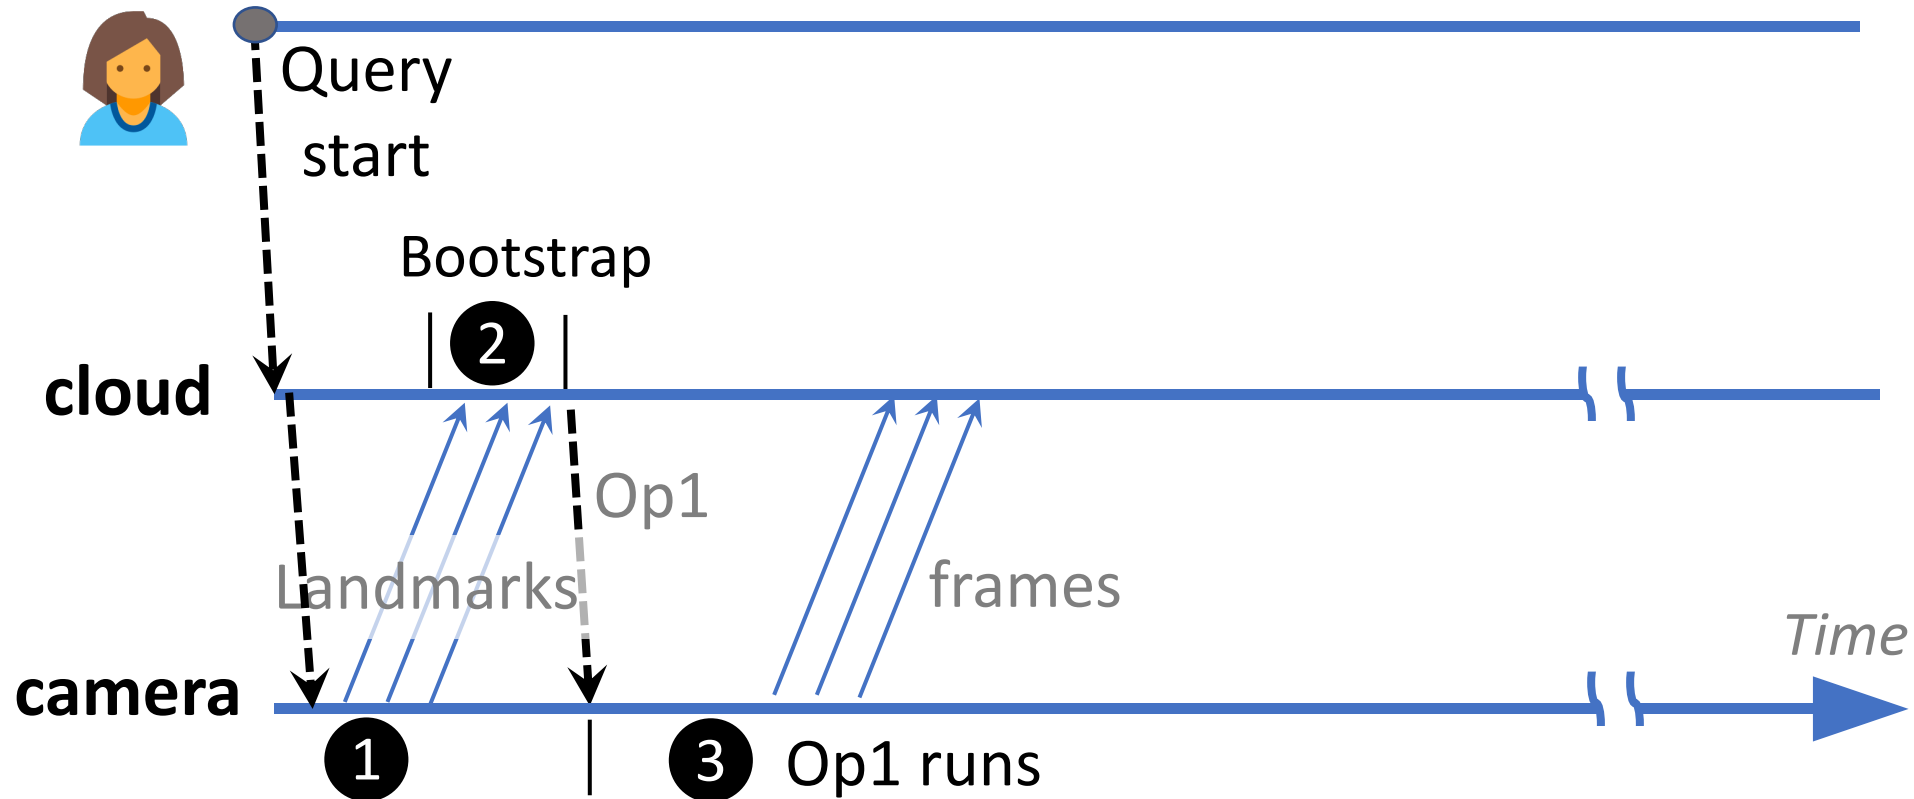

# Concrete execution plan

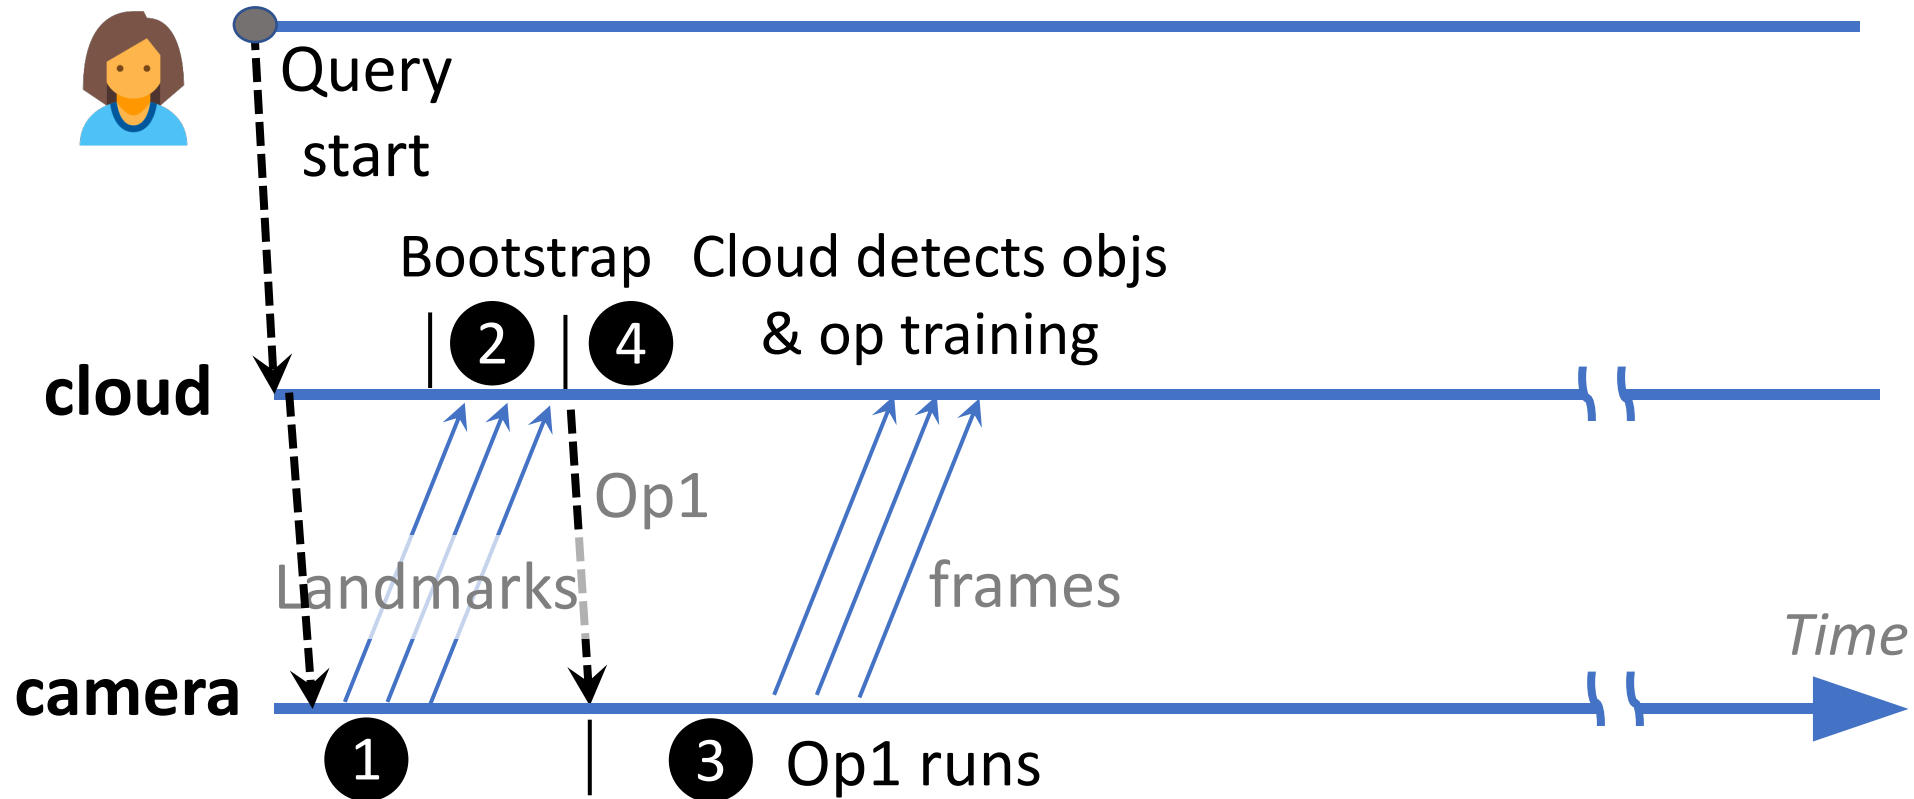

# Concrete execution plan

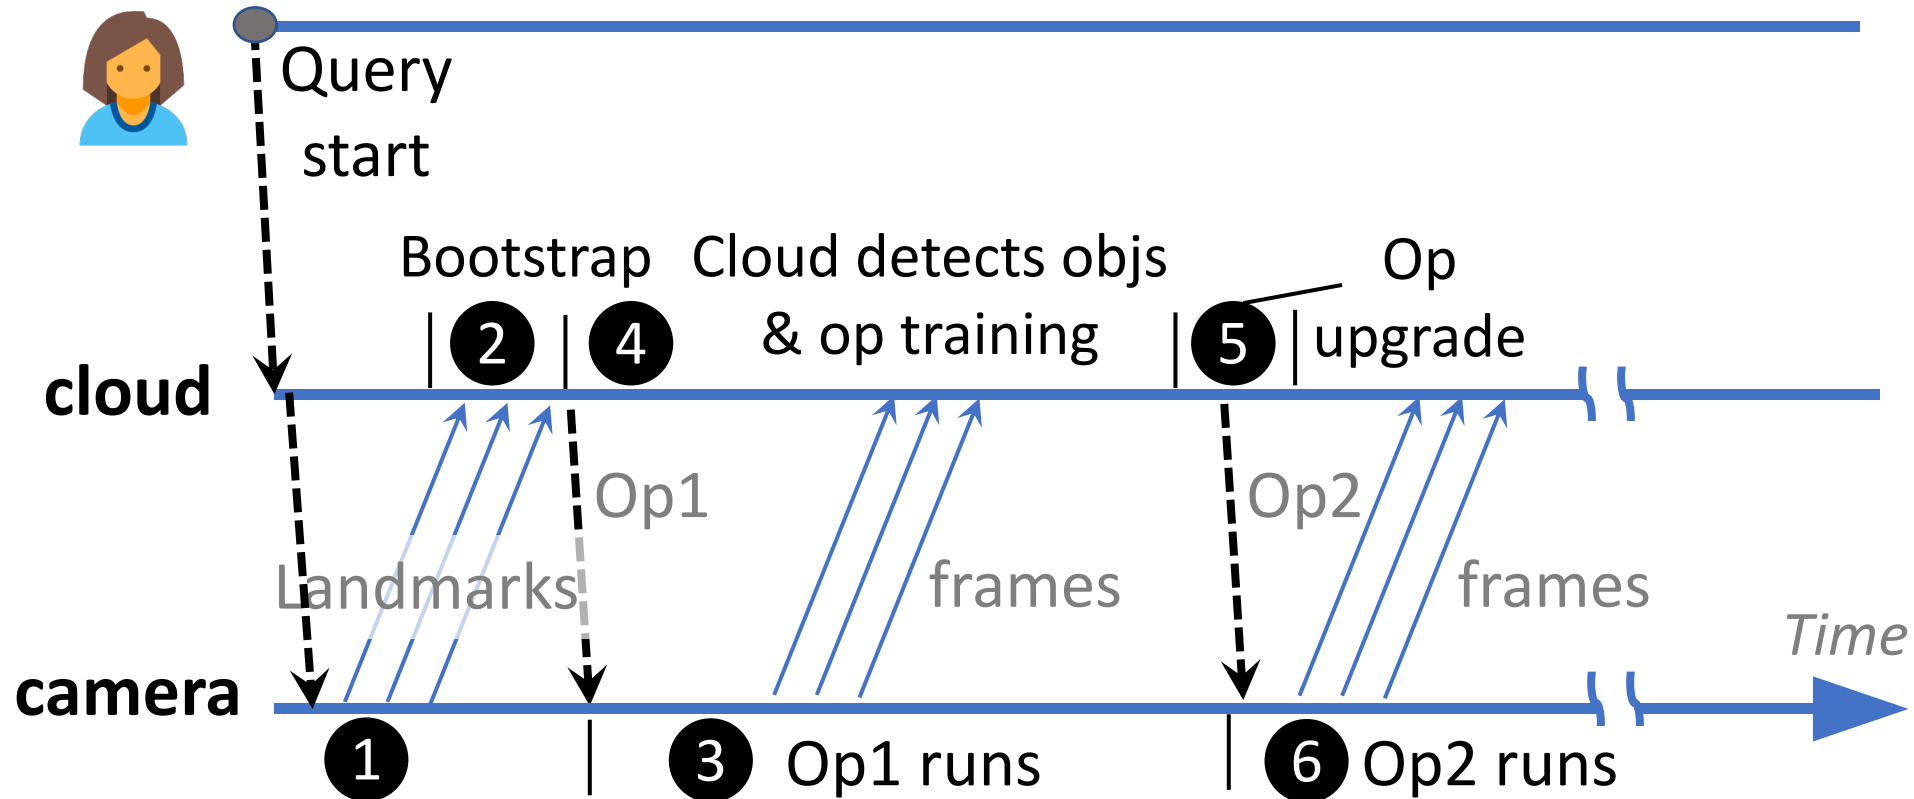

# Concrete execution plan

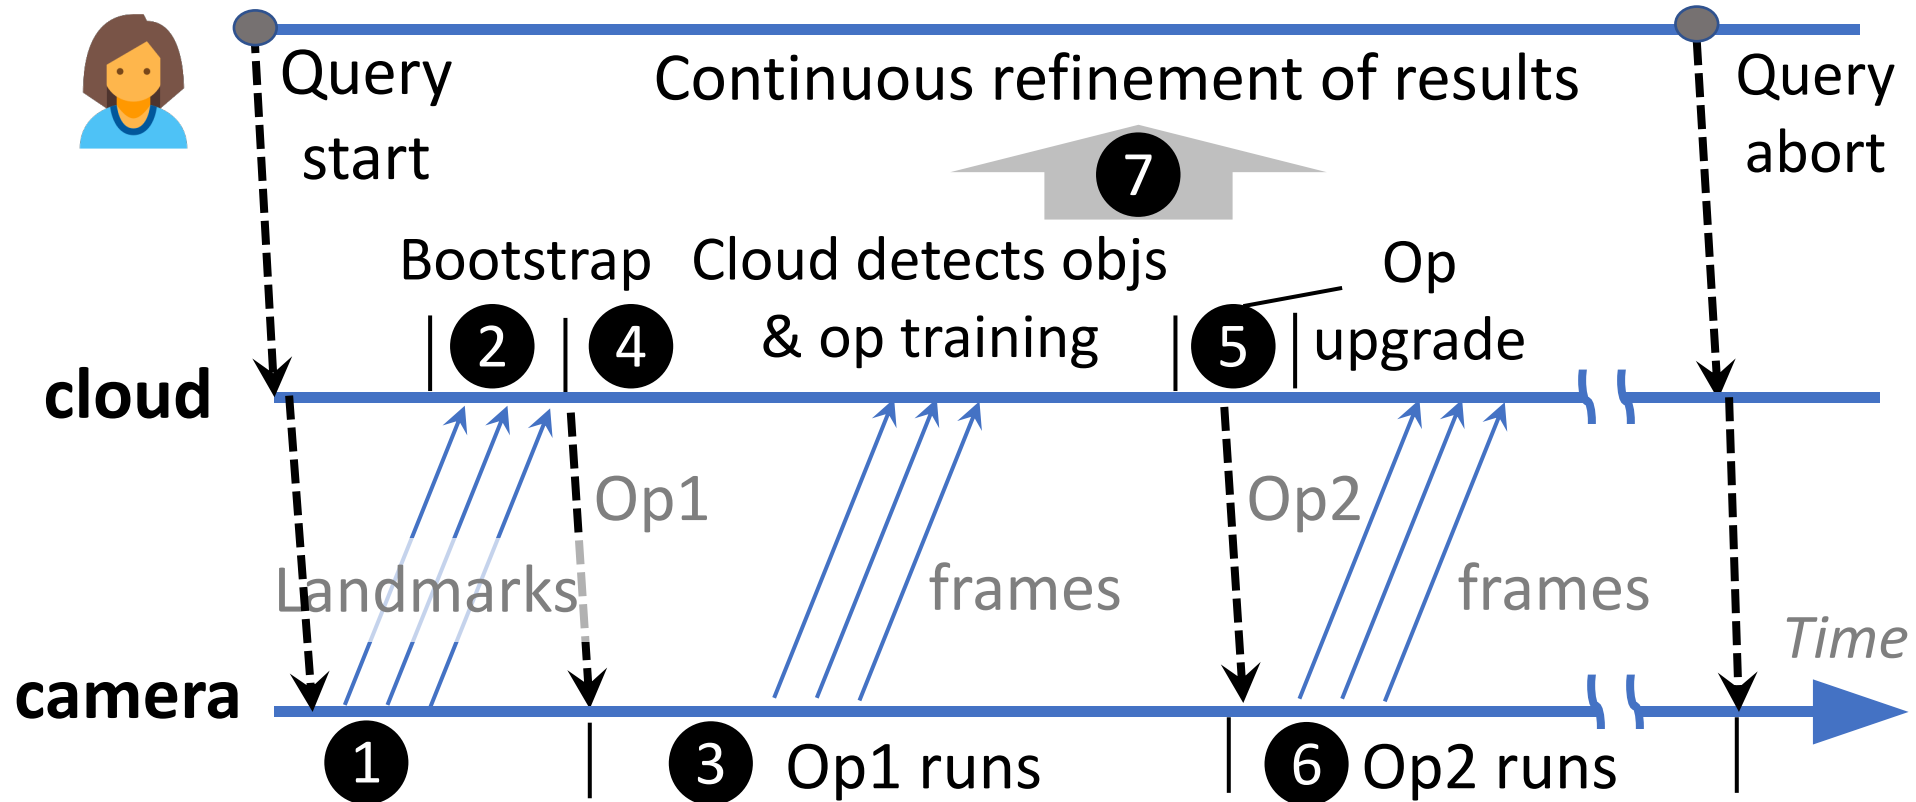

# Concrete execution plan

# Concrete execution plan

# Concrete execution plan

# Concrete execution plan

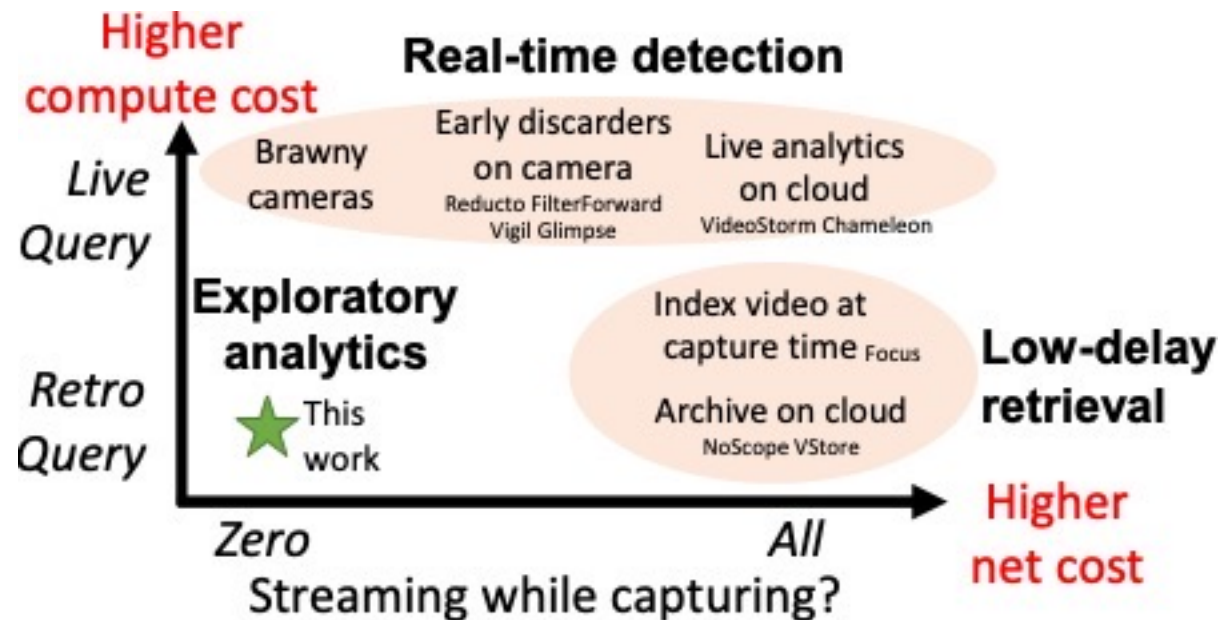

## **Detailed questions:**

- When to upgrade an operator?
- What operator to be upgraded to?
- What frames to be processed first?

*Please refer to our paper for details!*

# More about DIVA

- Scaled to more cameras? Just adding more GPUs.
- DIVA is complementary to real-time video analytics, which shall be deployed to critical regions, e.g., banks.

# Experiment settings

- 15 public video streams from YouTube
  - Per stream: 48 hours, 720P@1FPS

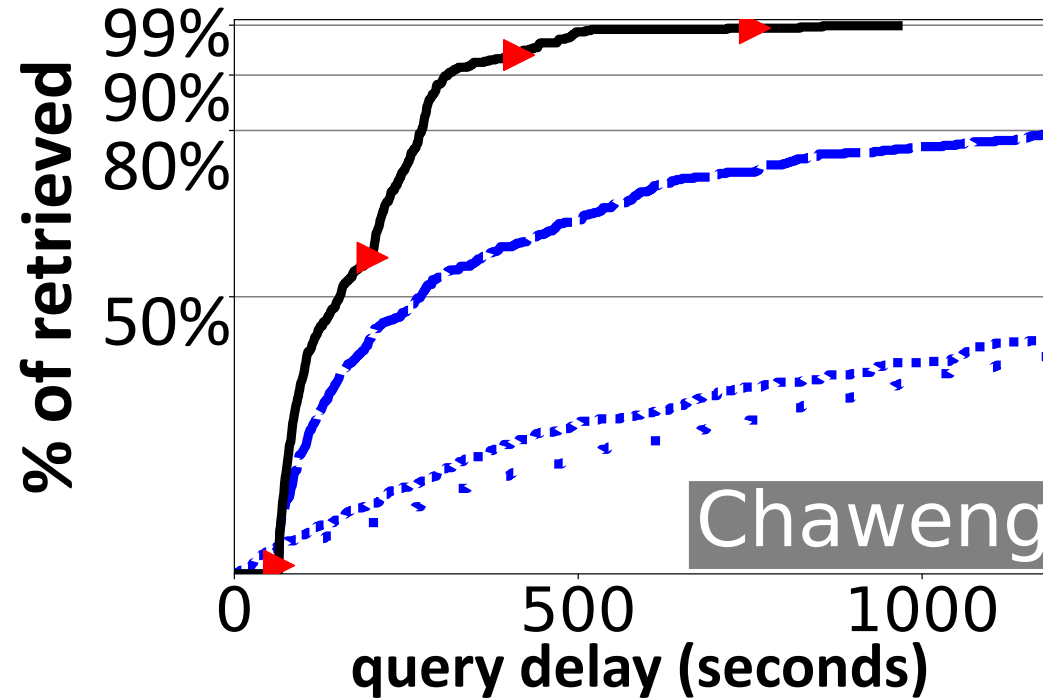

- Hardware: RPI 3B/Odroid XU4 (Camera) + Nvidia Titan V (Server)
- Network: 0.1-10MB/s (1MB/s by default)
- Baselines
  - CloudOnly, OptOp<sup>[1]</sup>, PreIndexAll<sup>[2]</sup>

[1] Kang, Daniel, et al. "Noscope: optimizing neural network queries over video at scale." *VLDB* 2017.

[2] Hsieh, Kevin, et al. "Focus: Querying large video datasets with low latency and low cost." *OSDI* 2018.

# Highlighted results

- DIVA outperforms the baselines throughout the query process

**Q: Retrieving frames containing a bicycle**

# Highlighted results

- DIVA improves end-to-end latency by **4X – 30X** to baselines

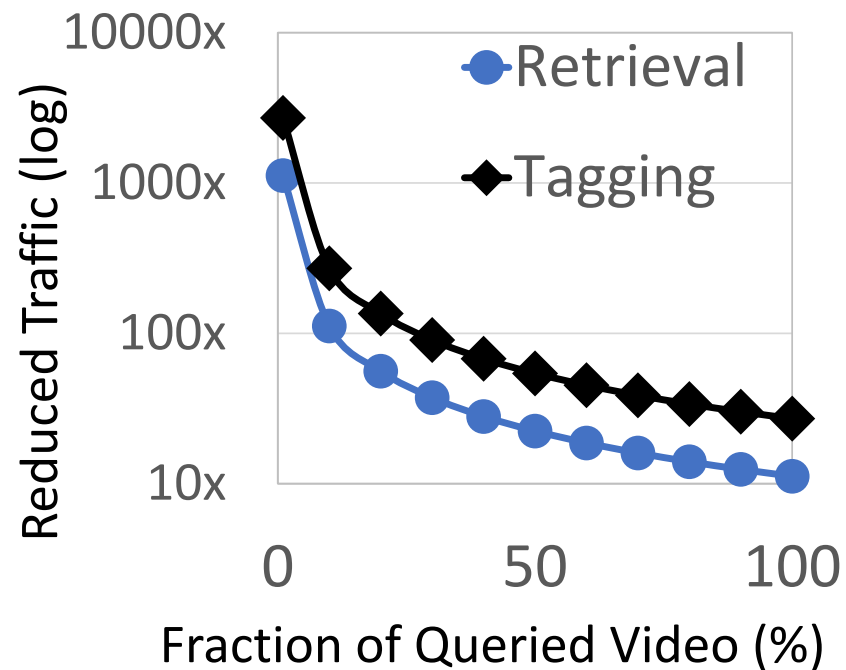

# Highlighted results

- Both two key designs of DIVA are critical, e.g., in Tagging:
  - Operator Upgrade brings **2.0X – 3.0X** speedup
  - Landmarks bring **1.6X – 3.1X** speedup

# Highlighted results

- DIVA saves network bandwidth over “all streaming” by **>1,000X** as in our campus case study.

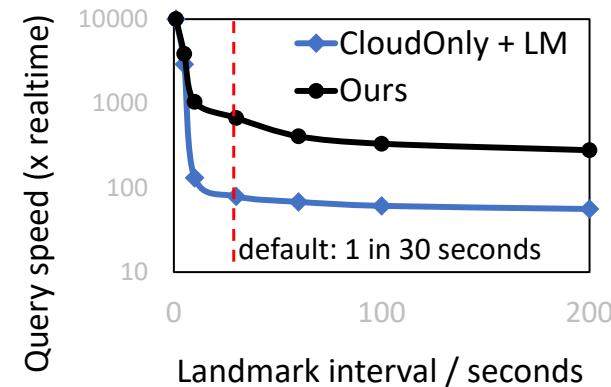

- *Most frames will not be queried*
- *Even for queried frames, most of them don't have to be uploaded*

# Highlighted results

- With sparser landmarks, DIVA's performance degrades **slowly**

- With inaccurate landmarks, DIVA's performance degrades **significantly**

# Summary

- Zero-streaming cameras towards high resource efficiency
  - A complement to cloud-centric approach
- **DIVA**: the first runtime for zero-streaming cameras
  - Key techniques: landmarks and operator upgrade
- Beyond cameras: cold data is pervasive (IoT, smartphones, etc)!
  - How to query them efficiently?
  - A new research direction?
