It’s with some regret that this is the final installment of my regular Python column. I suppose that I should offer some final words of wisdom, a historical retrospective, or maybe even a forward-looking “Python of the future” vision—however, I’m simply not that clever. Truth be told, I’m simply stretched a bit thin these days and think it would be a good time to step aside to make room for a fresh new voice and insights. So, in the spirit of leaving on a useful note, I thought I’d end on a practical trifle of a matter of some importance—the problem of getting a Python program to quit.

Bailing Out
Suppose your program has reached the final limit of what it can tolerate and you want it to die. To make it happen, raise a `SystemExit` exception and be done with it. For example:

```python
raise SystemExit(1)
```

It is standard practice to include some kind of numeric exit code, which indicates success (zero) or failure (non-zero) back to the process that launched Python. Alternatively, you can include a diagnostic message.

```python
raise SystemExit('Goodbye cruel world')
```

When you give a message, it is printed to `sys.stderr` and Python exits with a status code of 1. Problem solved—your program gracefully cleans up after itself and quits. Of course, that’s naturally not the end of the story or else this would be a pretty short article. Let’s continue.

Catching Exceptions
The `SystemExit` exception is not grouped with other exceptions. For example, it’s somewhat common to encounter code that catches all errors like this:

```python
try:
    something_complicated()
except Exception as e:
    print("It didn’t work. Reason: %s", e)
```

This code will catch most errors, but not `SystemExit`. If you wanted to catch that, you’d have to add an extra clause for it. For example,

```python
try:
    something_complicated()
except Exception as e:
    print("It didn’t work. Reason: %s", e)
except SystemExit as e:
    print("I see you’re going away")
raise
```

In practice, it’s rarely the case that you would ever catch `SystemExit` yourself. Even if you did, the most sensible action is perhaps to simply log the event and re-raise the exception as shown.
A common confusion is that sometimes programmers catch SystemExit by accident by writing sloppy exception handling code:

```python
try:
    something_complicated()
except:
    print("It didn’t work.")
```

This actually catches all possible errors, including SystemExit. However, this behavior is often unexpected and a potential source of obscure bugs. It’s usually best to catch just the exceptions you need as opposed to casting such a wide net.

**Keeping the Interpreter Alive**

For the purpose of debugging, sometimes it’s nice to keep the interpreter alive so that you can go poking around. Use `python -i` for that. It works even in programs that intentionally raise a SystemExit exception. You might see a message printed, but otherwise, you’ll be dropped into the interactive Python shell afterwards. From there, you can mess around. For example:

```bash
% python3 -i spam.py
Traceback (most recent call last):
  File "spam.py", line 5, in spam()
  File "spam.py", line 3, in spam
raise SystemExit("I’m dead")
SystemExit: I’m dead
```

**Cleanup Actions**

Sometimes you might want extra actions to take place upon program termination. For this, you can use the `atexit` module [1]. For example:

```python
import atexit

def goodbye():
    print("So long and thanks for all of the fish")
atexit.register(goodbye)
```

`atexit` allows you to register an arbitrary number of zero-argument functions that get fired upon termination of the Python interpreter. The functions execute in reverse order of registration. If you need to carry extra information, it is standard practice to use a `lambda` or `functools.partial` to do it. For example:

```python
def spam(name):
    atexit.register(lambda: print('Goodbye', name))
...
```

If needed, you can also unregister a previously registered function using `atexit.unregister()`.

**Cleanup with Context Managers**

On the subject of cleanup, when working with objects, it’s usually best to make use of context managers and Python’s with statement. For example, suppose you had some object that involved closing a resource such as a file or connection. A good way to clean it up is to give it `__enter__()` and `__exit__()` methods like this:

```python
class Spam(object):
    def __init__(self):
        self.resource = SomeResource()
    def __enter__(self):
        return self
    def __exit__(self, *args):
        # Cleanup
        self.resource.close()
```

With this object, you can now write code like this:

```python
with Spam() as s:
    ...
    # Use s
    ...
    # Resources released here
```

When control-flow leaves the indented block, the `__exit__()` method will run. This happens regardless of what happens in the block—including SystemExit.

**The `__del__` Puzzle**

Sometimes user-defined classes will define a `__del__()` method for the purposes of cleanup. For example:

```python
class Spam(object):
    def __del__(self):
        print("%s destroyed at %s" % (self, datetime.datetime.now()))
```

`__del__()` is a particularly troublesome method to be defining in general. The main problem is that you simply don’t know when it’s actually going to fire. This is especially true on program exit. When Python shuts down, all active objects get garbage collected—this includes functions, classes, and modules. In the above example, it’s entirely possible you could get a warning message like this printed to standard error:

```plaintext
Exception AttributeError: ‘NoneType’ object has no attribute ‘datetime’ in <bound method Spam.__del__ of <spam.Spam object at 0x1007d9f90>> ignored
```

What’s happened here is that the `datetime` module reference has already been garbage-collected and is no longer defined in global scope. The `__del__()` method blows up because `datetime`
is gone. This sort of thing can often be fixed by playing weird games with default arguments. For example:

```python
# spam.py
import datetime
class Spam(object):
    def __del__(self, now=datetime.datetime.now):
        print("%s destroyed at %s" % (self, now()))
```

Ugh. Explaining something like that to your coworkers is going to be hard and even then, it’s no guarantee that it’s going to work (what if the now() function itself needs other functionality that’s already been garbage-collected?). The bottom line is don’t rely on __del__() to perform cleanup actions properly when it comes to program exit. You’re better off considering a context manager or a more explicit approach.

**Threads**

Program exit becomes much more interesting when you start programming with threads [2]. Consider the following code:

```python
import threading
import time
def countdown(n):
    while n > 0:
        print('T-minus', n)
        time.sleep(5)
        n -= 1
threading.Thread(target=countdown, args=(5,)).start()
raise SystemExit("Goodbye")
```

If you run this, program termination is delayed until the thread runs to completion. In fact, if you had a lot of threads, program exit won’t occur until all of them terminate.

This situation is made even more unfortunate given that there is no mechanism for terminating or signaling a thread once started. Your only sane recourse is to build in some kind of periodic polling or check.

```python
import threading
import time
main_thread = threading.current_thread()
def countdown(n):
    while n > 0 and main_thread.is_alive():
        print('T-minus', n)
        time.sleep(5)
        n -= 1
threading.Thread(target=countdown, args=(5,)).start()
raise SystemExit('Goodbye cruel world')
```

Alternatively, you could create the thread as “daemonic” like this:

```python
import threading
import time
def countdown(n):
    while n > 0:
        print('T-minus', n)
        time.sleep(5)
        n -= 1
threading.Thread(target=countdown, args=(5,), daemon=True).start()
raise SystemExit("Goodbye")
```

Daemonic threads are killed immediately once the main thread exits. This is not without its own set of concerns, however. Daemonic threads killed in this way do not exit gracefully. For example, they don’t garbage-collect remaining objects (they don’t execute __del__() methods), and they don’t run the __exit__() method of context managers. So if you were expecting some kind of graceful cleanup from this, don’t.

Curiously, functions registered with atexit will still run upon termination of a threaded program—even if registered by daemonic threads. So you could write code like this:

```python
import threading
import time
import atexit
def countdown(n):
    onexit = lambda: print('Thread dead. Final value', n)
atexit.register(onexit)
    while n > 0:
        print('T-minus', n)
        time.sleep(5)
        n -= 1
atexit.unregister(onexit)
threading.Thread(target=countdown, args=(5,), daemon=True).start()
time.sleep(12)
raise SystemExit('Goodbye cruel world')
```

When you run this, you’ll see a message about a final value of 3.

**Keyboard Interrupts and Signals**

One especially nasty problem with program termination is the handling of keyboard interrupts (Control-C) and signals [3]. These events often ultimately result in program termination, but unlike a typical SystemExit exception, they occur asynchronously. This means that they could potentially occur on any statement in your program.

Perhaps the most important thing to note about signals is that they are only handled by Python’s main execution thread. There
are situations where it is impossible to receive signals and it will appear as if it is impossible to kill your program. The most common scenario is if the main program gets tied up on a lock or becomes busy with some CPU-intensive task. Here is a simple example you can try:

```python
>>> 'a' in range(1000000000)  # Use xrange on Python2
<Ctrl-C>
```

In this example, you’ll find that the code becomes totally unresponsive to the keyboard interrupt until the operation completes. Under the covers the interpreter is tied up with a big calculation taking place in C. There’s just no opportunity for it to be interrupted.

More diabolical situations can arise with combinations of locking and signal handling. Consider this interesting bit of code involving the logging module:

```python
import logging
import time
import signal

log = logging.getLogger(__name__)

def goodbye(signo, frame):
    log.debug('Goodbye')
    raise SystemExit()

def spin():
    while True:
        log.debug('Hey %f' % time.time())

signal.signal(signal.SIGINT, goodbye)
logging.basicConfig(level=logging.DEBUG)
spin()
```

In this code, a constant stream of log messages is quickly emitted until terminated by a Control-C (SIGINT). It might look innocent enough and it might even seem to work when you try it. However, there are hidden dangers. It turns out that the logging module internally uses thread locks. If you run this program repeatedly, killing it with Control-C, you might find that just every so often, instead of dying, the whole program freezes. What happened? The main program was in the middle of logging a message with the lock held when a signal arrived. The signal handler then tried to log a message, but is now deadlocked due to the logging lock being in use. Your only recourse here—open up another terminal and kill Python using `kill -9`.

Some general advice concerning threads, signals, and program exit. If you want your program to terminate, a sensible strategy is often one that keeps the main-thread free for nothing other than signal handling. Use it to catch keyboard interrupts and other signals and have it arrange to have the rest of the program exit in the most graceful manner that you can devise. This is only a simple template:

```python
import threading
import time

terminated = False

def countdown(n):
    while n > 0 and not terminated:
        print('T-minus', n)
        time.sleep(5)
        n -= 1

threading.Thread(target=countdown, args=(5,)).start()
# Main-thread. Spin and wait for termination

try:
    while True:
        time.sleep(1)
finally:
    terminated = True
```

There are many variations on this theme, but if you’ve got a very complicated application and it involves concurrency, directing all asynchronous signals and/or the keyboard interrupt to a single well-defined place is probably a good strategy.

**The Nuclear Option**

Finally, if all else fails, there is always `os._exit()`. For example:

```python
import os; os._exit(1)
```

This is a direct line to the underlying `exit()` system call. It will terminate Python immediately, with no cleanup of any kind. As a general rule, though, you’d probably want to avoid this except as a last resort.

**Final Words**

As noted, this is my last installment of the regular Python column. I’d just like to thank Rik Farrow and everyone else at USENIX for their support over the last six years and hope that you’ve enjoyed it. I intend to stay active in the Python community, so say hello if you ever see me at a conference, or if you happen to be in the Chicago area, please feel free to look me up. Until then, happy Python hacking!
